It is difficult to compare the gains of the past year with those realized immediately after World War I, because that war ended later in the year and the Bureau's study was then as of May 15, rather than as of July 1. However, by May 15, 1919, 6 months after the end of World War I, rates had risen about 15 percent over May 15, 1918, in comparison with an increase of over 11 percent recorded in the 11 months after World War II. In view of the removal of all wage controls following Executive Order 9081 of November 9, 1946, there may be substantial wage increases in the near future. During a comparable period after World War I (1919–20), when there was also a great construction program, union scales advanced 35 percent.

The 11-percent wage increase for journeymen between 1945 and 1946 was slightly less than that for all trades combined, although the gain for helpers and laborers was substantially more (16 percent). Of the 27 journeymen trades studied 18 reported average increases exceeding 10 percent (table 3). Foremost among these were trades essential in all types of construction: Carpenters, bricklayers, composition roofers, painters, and plasterers. Larger increases were recorded for such trades as granite cutters, but these trades were relatively unimportant in the current construction program or had relatively few workers compared to the carpenters and bricklayers.

TABLE 3.—*Percent of increase in union building-trades wage rates, by trades, July 1, 1945, to July 1, 1946*

Trade	Percent of increase
All trades	11.5
Journeymen	10.8
Asbestos workers	9.9
Boilermakers	7.9
Bricklayers	11.4
Carpenters	12.4
Cement finishers	12.3
Electricians (inside wiremen)	6.9
Elevator constructors	6.5
Glaziers	9.9
Granite cutters	20.5
Lathers	11.4
Machinists	11.5
Marble setters	11.1
Mosaic and terrazzo workers	13.1
Painters	10.6
Paperhangers	11.1
Plasterers	10.6
Plumbers and gas fitters	8.1
Rodmen	10.4
Roofers, composition	11.4
Journeymen—Continued.	
Roofers, slate and tile	8.7
Sheet-metal workers	12.3
Sign painters	12.6
Steam and sprinkler fitters	9.1
Stonecutters	13.6
Stonemasons	13.6
Structural-iron workers	8.8
Tile layers	13.2
Helpers and laborers	16.2
Bricklayers' tenders	16.3
Building laborers	17.2
Composition roofers' helpers	13.1
Elevator constructors' helpers	6.3
Marble setters' helpers	15.4
Plasterers' laborers	12.7
Plumbers' laborers	13.9
Steam and sprinkler fitters' helpers	13.7
Terrazzo workers' helpers	17.4
Tile layers' helpers	16.2

Electricians and plumbers—critical groups in the current construction program—had comparatively small gains owing primarily to the fact that large unions of plumbers and electricians in New York City maintained their wartime hourly rate of $2.00. Most other New York City unions obtained increases of about 25 cents an hour.

AVERAGE HOURLY WAGE RATES, JULY 1, 1946

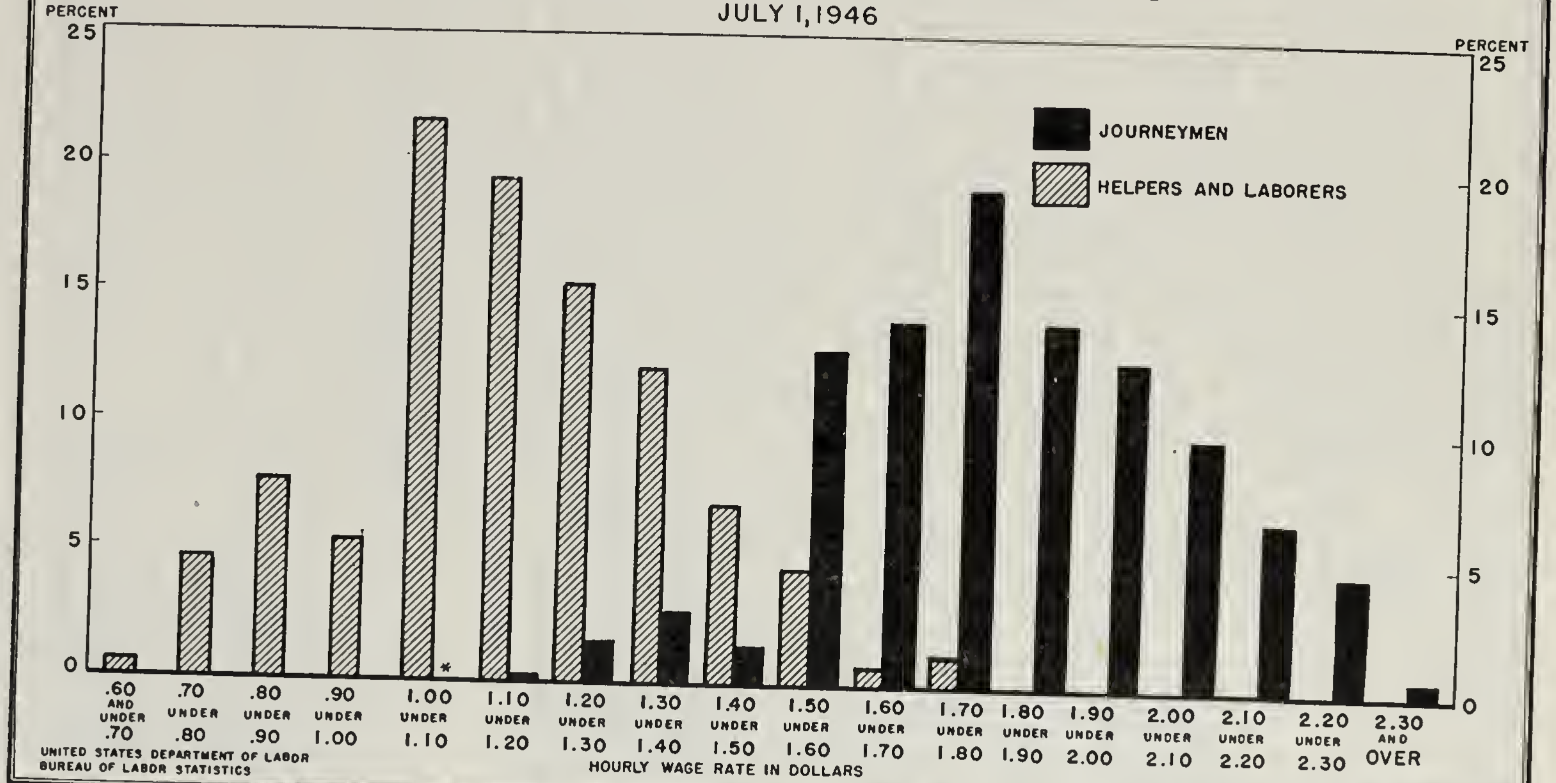
Building-trades workers surveyed on July 1, 1946, averaged $1.67 an hour, as a whole; journeymen made $1.79 and helpers and laborers $1.14 (table 4). The serious shortage of bricklayers in some areas may account in some degree for their ability to negotiate rates well above a number of the other trades. Stonecutters, a trade with very little work in the current construction program, had a rate nearly as high, however. Stonemasons, with the third highest average, in most instances belong to the bricklayers' union and generally receive the same scale as bricklayers. Lathers, plasterers, and plumbers likewise had averages exceeding $1.90 an hour. Paperhangers, on the other hand, had the lowest rate among journeymen ($1.60).

Almost half of the journeymen received between $1.60 and $1.90 an hour and over a fifth $2.00 or more, whereas less than 6 percent fell below $1.50. The most frequently reported rate was $1.75.

CHART 2

DISTRIBUTION OF UNION BUILDING TRADES WORKERS ACCORDING TO HOURLY WAGE RATES

JULY 1, 1946



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

* LESS THAN ONE TENTH OF ONE PERCENT

Table 4.—*Distribution of union members in the building trades, by hourly wage rates, July 1, 1946*

[1] Minimum rate $1 per hour.
[2] Maximum rate $2.79 per hour.
[3] Less than a tenth of 1 percent.
[4] Minimum rate $0.600 per hour.
[5] Maximum rate $1.750 per hour.

Among journeymen, only boilermakers, bricklayers, and stonemasons had no members working for less than $1.60 an hour, and each of these trades had a substantial number of workers above $2.00. In 9 trades, a third or more of the workers were rated at $2.00 or more, including 70 percent of all bricklayers. The lowest rate, $1.00 an hour, generally covered either roofers or glaziers and included only 228 workers. The highest rate was $2.79, paid to sign painters on outdoor advertising in New York City.

Steam and sprinkler fitters' helpers had the highest average rate among the helpers' and laborers' groups, which was explained by the very heavy membership in New York City, where the union rate was $1.73.[3] The composition roofers' helpers had the lowest average. The building-laborer classification was most important as it included about 65 percent of all helpers and laborers studied.

Over two-thirds of all helpers and laborers received between $1.00 and $1.40 an hour. About a fifth had rates between 60 cents and $1.00, and an eighth received between $1.40 and $1.80. The lowest hourly rate scale (60 cents) applied to building laborers in Jackson, Miss., the highest ($1.75) to plasterers' laborers in San Francisco.

CHANGES IN UNION WAGE RATES BETWEEN 1945 AND 1946

The 12-month interval between the surveys of July 1, 1945 and 1946, witnessed the cessation of hostilities, an advance in the cost of living, a tremendous building-construction program, acute shortages in numerous commodities (including building materials), and intense union activity to secure improvements in basic wage rates. The forces at work manifested themselves in the current study particularly by the marked shifts in ratios revealing the extent and magnitude of rate changes.

On July 1, 1945, a third of the building-trades members for whom comparable quotations were received reported wage increases since the prior study date. By July 1, 1946, almost 89 percent of the comparable quotations tabulated, embracing all but 4 percent of the comparable membership, showed wage boosts. Whereas advances of 10 percent and over affected less than 6 percent of all members on July 1, 1945, the proportion so benefiting rose to almost 70 percent on July 1, 1946.

Principal trades which led both in the proportions of quotations howing increases and the percentage of members benefiting by rate aises were the bricklayers, carpenters, and building laborers.

---

[3] These workers will probably be excluded in future reports, as the helper system is being eliminated by ne Plumbers and Steamfitters' International Union (United Association of Journeymen Plumbers and teamfitters of the United States and Canada, AFL).

A majority of the journeymen and of the helpers benefited by rate gains of 10 to 20 percent.[3] The helper group predominated in the categories with increases of 20 percent or more, 34 percent of their members falling therein,[4] as contrasted with 4 percent of the journeymen.

TABLE 5.—*Percent of union members affected by wage rate changes and extent of increases, July 1, 1946, compared with July 1, 1945*

Trade	Percent of union members affected by—		Percent of total members affected by increase of—					
	No change	Increase	Less than 5 percent	5 and under 10 percent	10 and under 15 percent	15 and under 20 percent	20 and under 25 percent	25 percent and over
All building trades	4.3	95.7	2.5	23.7	40.9	18.7	6.4	3.5

Composition roofers' helpers	18.4	81.6	9.0	9.0	11.7	9.0	27.2	15.7
Elevator constructors' helpers	25.0	75.0	4.6	50.5	11.4	8.2	.3	------
Marble setters' helpers	9.6	90.4	------	8.0	26.2	34.2	8.0	14.0
Plasterers' laborers	4.0	96.0	2.0	29.0	32.6	12.6	12.2	7.6
Plumbers' laborers	15.0	85.0	------	5.5	25.6	28.0	15.1	10.8
Steam and sprinkler fitters' helpers	5.3	94.7	------	1.2	7.3	85.4	.8	------
Terrazzo workers' helpers	2.0	98.0	------	8.6	17.6	44.5	7.6	19.7
Tile layers' helpers	7.8	92.2	------	14.2	29.6	12.9	9.0	26.5

Considerable segments of important trades registered gains between 10 and 20 percent, notably bricklayers (68.6 percent), carpenters (80.6), sheet-metal workers (73.5), painters (52.2), plasterers (53.2), and building laborers (56.7).

---

[4] This was the result, in the main, of increases up to 37½ cents an hour to helpers in cities with low basic scales and/or high membership concentration.

Elevator constructors and their helpers, plumbers, and electricians ranked highest in membership proportions working under quotations involving no wage changes. No decreases in wage rates during the year were reported in any of the 75 cities surveyed.

POST SURVEY RATE CHANGES

From July 2 until November 9, 1946 (the termination date of wage controls), the Wage Adjustment Board approved increases benefiting almost a fourth of the workers included in the July study. These raises, not reflected in any of the tables appearing in this report, averaged 15 cents an hour, and lifted the general average to $1.71 on November 9, a gain of approximately 2 percent for each of the two groups. Inclusion of these later increases would advance the index of union hourly wage rates for all workers to 132.0 on November 9 (journeymen, 129.5; helpers, 149.5). During the period from the end of the war to the end of wage controls, union building-construction wage rates advanced about 14 percent.

UNION WAGE RATES BY CITY AND REGION

As in previous years, the highest city averages[5] for journeymen were found in the New York metropolitan area (table 6). The average for the adjacent city of Newark was slightly above that for New York, which may have been caused by the higher electricians' scale in Newark, as other important trades have about the same scales in these two cities. Chicago ranked third with respect to journeymen workers. Butte, Mont., one of the smallest cities surveyed, was highest among the cities of 40,000 to 100,000 population and ranked eleventh among the 75 cities studied. For journeymen, Charlotte, N. C., and Jackson, Miss., had the lowest city averages.

In 52 of the 75 cities studied the average increases for journeymen etween 1945 and 1946 were over 10 percent.[6] Charlotte, N. C., nd Houston, Tex., with increases of approximately 17 percent each, ad the largest average gains for this group, Charleston, S. C., the mallest (less than 6 percent).

---

[5] The averages presented were weighted according to the number of members in each local union covered y the reported rates and, in many cases, may be lower than a simple average of specific rates owing to the rge memberships in the less-skilled trades carrying the lower rates.

[6] These net changes were based on the specific rates for 1945 and 1946, weighted by the membership for ch union in 1946. Only those quotations showing comparable data for both years were included. As uilding-trades hourly wage rates in normal years tend to be changed by additions of either 12½ or 10 cents, ecific increases for 1946 will reflect larger percentage changes among those trades with comparatively low ales. For this reason cities which have lower scales tend to show the greatest percentage increases.

TABLE 6.—*Average union hourly wage rates in the building trades, by cities and population groups, July 1, 1946*

City and population group	Average hourly rate
Journeymen	
Population group I (over 1,000,000):

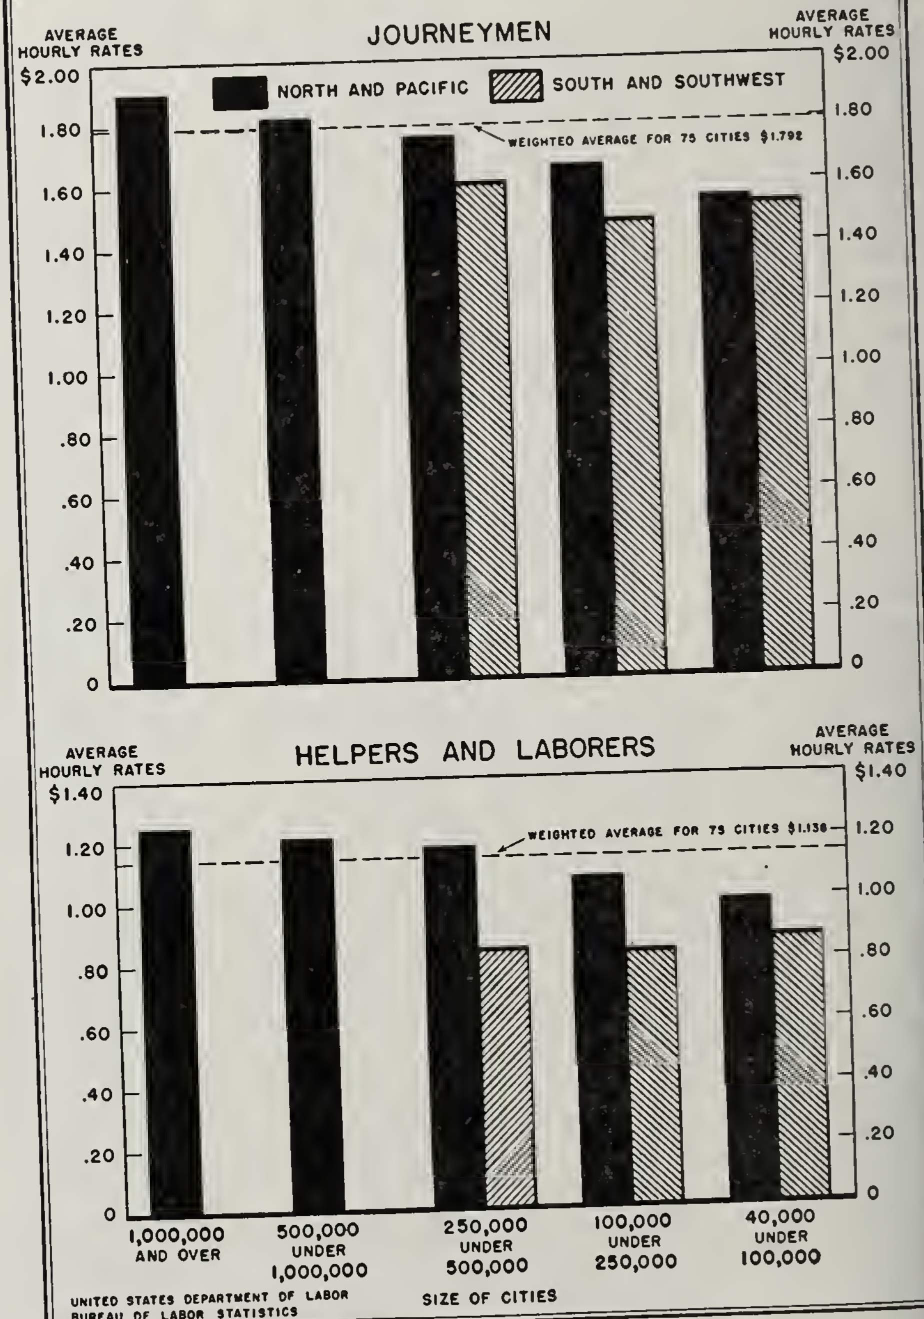
CHART 3

AVERAGE UNION WAGE RATES IN BUILDING TRADES ACCORDING TO SIZE OF CITY AND REGION

JULY 1, 1946



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

New York and Newark, as in the case of journeymen, also had the highest average rates for helpers and laborers; Mobile, Ala., and Jackson, Miss., were the lowest for helpers and laborers. With few exceptions (generally the highest-wage cities), there seemed to be little relationship between the level of rates for journeymen and helpers. Washington, D. C., for example, had the highest average for journeymen among cities of 500,000 to 1,000,000 population but next to the lowest for helpers and laborers.

In many cities substantial percentage increases were recorded during the year for the helper and laborer groups. The rise of 42 percent in Charleston, S. C., was due to the advance in building laborers' rates from 50 to 75 cents. In Houston, the increase of about 33 percent resulted from changes in rates for building laborers (from 60 to 80 cents an hour) and for other trades (from 75 cents to $1.00). Other increases of over 25 percent were found in Jacksonville, Memphis, Oklahoma City, Tampa, and Youngstown. The only city showing no increase in the helper and laborer group was Mobile.

Wage rates for building construction workers as a whole were consistently higher in the larger cities. Substantially higher averages were recorded for most building-trades workers in the North and Pacific region as compared with the South and Southwest area (chart 3). The differential for all journeymen trades combined amounted to about 15 cents in group III cities, 18 cents in group IV cities, and about 2 cents in the smallest or group V cities. The largest differences were found in the helper and laborer group, where the averages shown for the North and Pacific region were almost 34 cents higher in group III cities, 24 cents in group IV cities, and 12 cents in group V cities.

Cities in the North and Pacific area had higher journeymen averages than cities in the South and Southwest region in 62 of 74 possible comparisons. With the single exception of elevator constructors' helpers in the group V cities, all 19 comparable averages for helpers and laborers were also substantially higher in the North and Pacific section than in the South and Southwest. The higher average for elevator constructors' helpers among group V cities in the South and Southwest was due to a rate of $1.38 an hour in Phoenix compared with a rate of $1.02 in Portland, Maine.

TABLE 8.—*Average union wage rate in each building trade by regional and population group, July 1, 1946*

Trade	Cities in population group [1]										
	Group I [2]	Group II [2]	Group III			Group IV			Group V		
	North and Pacific	North and Pacific	All cities	North and Pacific	South and Southwest	All cities	North and Pacific	South and Southwest	All cities	North and Pacific	South and Southwest

[1] Group 1 includes cities over 1,000,000 population; group II, 500,000 to 1,000,000; group III, 250,000 to 500,000; group IV, 100,000 to 250,000; and group V, 40,000 to 100,000.
[2] No city of this size in the South or Southwest.
[3] Insufficient quotations to compute an average.

Overtime and Sunday Rates

After the war most building-trades unions returned to prewar standards regarding overtime and Sunday rates. During the war, time and a half for overtime was the general practice as a result of the wartime stabilization agreement between the contracting agencies of the Federal Government and the Building and Construction Trades Department of the American Federation of Labor.

[1] Less than a tenth of 1 percent.

In July 1946, over three-fifths of the journeymen received double he basic rate if they were required to work other than regular hours. n this industry, this generally means after 8 hours per day, 40 hours er week, on Saturdays, or beyond specified daily hours such as after p. m. or before 8 a. m. Only 8 trades had a majority of their members covered by an overtime rate of time and a half. In 7 trades, over

90 percent of the membership was included under double-time rates. About 9 of every 10 journeymen received double time if required to work on Sunday.

The situation was different for helpers and laborers, as only about a fourth of the workers received double pay for work at other than regular hours; about three-fourths received time and a half. If required to work on Sunday, however, 9 out of 10 helpers and laborers received double time, their proportion equaling that of journeymen.

Weekly Hours

TREND OF STRAIGHT-TIME WEEKLY HOURS, 1946

On July 1, 1946, straight-time weekly hours averaged 39.2 for all building-trades workers; journeymen averaged 39.1 hours and helpers and laborers 39.5 (table 12). Over four-fifths of the journeymen were on the standard 40-hour week; most of the others had a 35-hour week. Electricians, plasterers, and plumbers were the only trades with a substantial percentage of members on the 30-hour week, largely owing to the 30-hour straight-time week for these trades in New York City. Nine out of every 10 helpers and laborers were covered by the 40-hour week.

TABLE 10.—*Indexes of union weekly hours in all building trades, 1907–46*

[1939=100]

Year	All trades	Journeymen	Helpers and laborers	Year	All trades	Journeymen	Helpers and laborers
1907	124.3	123.8	126.1	1927	114.7	114.8	113.9

1916	117.2	117.1	117.2	1936	101.5	101.5	101.4
1917	116.9	116.9	116.7	1937	101.9	101.9	101.8
1918	116.3	116.2	116.3	1938	100.2	100.1	100.2
1919	115.7	115.7	115.2	1939	100.0	100.0	100.0
1920	115.1	115.2	114.5	1940	99.9	100.0	99.4
1921	115.0	115.1	114.5	1941	100.3	100.5	99.7
1922	115.0	115.2	114.2	1942	101.1	101.8	98.8
1923	115.1	115.3	114.4	1943	101.0	102.0	98.1
1924	115.1	115.3	114.4	1944	101.2	102.2	98.1
1925	115.1	115.3	114.2	1945	101.2	102.2	98.1
1926	114.9	115.1	113.9	1946	100.2	101.1	97.4

Straight-time weekly hours for all building-trades workers declined about 1 percent during the year, bringing the index to 100.2—very close to the 1941 figure (table 10). This reduction was caused by the termination of the agreement between the unions and the Government which established the 40-hour week,[7] and by the transfer of workers from Government to private projects. Prior to the war, many unions had straight-time workweeks of less than 40 hours and in general did not require overtime pay for hours up to 40 per week on either Federal or private work during the war. Because of the large volume of work available at the present time, some of these unions continued their 40-hour week agreements.

---

[7] An agreement between the Building and Construction Trades Department of the American Federation of Labor and the Contracting Agencies of the United States Government, dated May 22, 1942, and effective July 1 of that year, stabilized wages and established the straight-time 40-hour week on all Government projects.

Tile layers' helpers	40.0	.1	---	---	99.9	---	---

[1] Less than a tenth of 1 percent.

Straight-time hours for journeymen fell somewhat more than for helpers and laborers, because very little adjustment was necessary in 1942 to bring the helpers to a 40-hour week, whereas greater adjustment was necessary for the journeymen. The greatest hourly reduction recorded (7 percent for steam and sprinkler fitters' helpers) resulted from a decrease in hours (from 40 to 35) in New York City.

Apprentices

Typical of the significant changes brought about by the postwar boom in the construction industry was the indication (by more than 1,050 building-trades locals in the cities surveyed) that there were approximately 9 active journeymen for each apprentice in July 1946, contrasted with a ratio of almost 34 to 1 a year earlier. Proportions of apprentices to journeymen ranged from less than 2 percent for stonecutters and stonemasons to 23 percent for asbestos workers. Exceeding the over-all average of 9 to 1 were the electricians, cement finishers and plasterers, and sheet-metal workers, with about 5 journeymen to each apprentice. A low ratio was recorded for painters and paperhangers—1 apprentice to more than 20 journeymen. Significant increases in the apprentice labor force were reported by the carpenters, bricklayers, cement finishers, lathers, plasterers, and sign painters.

Trade practices, labor-market conditions, and custom exert far greater influence on apprentice-journeymen ratios than size of trade membership. Carpenters, with the largest membership tabulated, had about 1 apprentice for each 10 journeymen, whereas asbestos workers, with about 2 percent as many members as the carpenters, reported about 1 apprentice for every 4 journeymen.

Over two-fifths of the locals queried reported that union regulations permitted further expansion of the apprentice force over the number employed July 1, 1946. This group included virtually all of the granite and the stonecutters' locals, about two-thirds of the cement inishers' and plasterers', and half of the lathers' and roofers' unions. Among the 22 cities in which at least 50 percent of the building-rades locals indicated that opportunity for expansion existed were Chicago, New York, Philadelphia, Pittsburgh, and San Francisco. On the other hand, more than three-fifths of the locals of boilermakers, bricklayers, electricians, glaziers, plumbers, and sheet-metal workers eported that apprentice membership could not be further increased. Two-thirds of the locals contacted stated that they would not favor mploying more apprentices than their existing ratios permitted. n contrast, significant proportions (although in no case a majority) f the bricklayers', cement finishers' and plasterers', lathers', and oofers' locals favored the employment of more apprentices than llowed by present ratio. Two of the numerically small trades had majority of the locals on record as favoring an expansion of the pprentice ratios.

Better than 7 of every 10 locals tabulated have established appren- ce programs in cooperation with employers or their associations and ave registered these programs with either a State or Federal ap- rentice agency. About two-thirds of the locals reported that the erage apprentice rate, considered as a percentage of the journeyman te, was higher in July 1946 than in 1939.

Union Participation in Residential Construction

Seventy-three percent of the building-trades locals reported that they negotiated agreements covering most of the residential construction work in their areas. At least 8 out of 10 locals of building laborers, painters and paperhangers, electricians, carpenters, and plumbers, and a slightly lower proportion of bricklayers, cement finishers and plasterers, glaziers, and sheet-metal locals indicated that they controlled the bulk of residential work in their territory. On a geographical basis, more than half of the unions in 60 cities (44 in the North and Pacific region, 16 in the South and Southwest) had jurisdiction over the major portion of residential work in their localities. In only 8 cities did all of the unions claim to control a majority of this branch of the work.

Almost all the locals reported that their agreements make no provision for lower scales for residential work. According to union officials contacted in the 75 cities surveyed, over 250,000 organized building-trades workers were engaged on residential construction on July 1, 1946, of whom about 89 percent were working under union agreement; the remainder were employed with union sanction. Substantial majorities of the locals asserted that residential work not under union agreement on July 1, 1946, did not generally command lower scales than either union or nonunion commercial work or union residential work.

In two cities (in Pennsylvania), however, all the locals maintained that residential work not under union agreement commanded lower scales than nonunion commercial work. All of the locals in 7 cities reported that such scales were lower than union commercial rates, and in 9 cities each of the locals claimed that lower scales generally prevailed for nonunion residential work than for such work under union agreement.

A Digest of The Development and Activity of The Wage Adjustment Board for The Building Construction Industry

The Wage Adjustment Board for the building and construction industry was originally set up in May 1942, several months before wage controls for other industries were introduced. The Board was established in the Department of Labor as a result of the voluntary agreement entered into on May 22, 1942, between the Building Trades Department of the American Federation of Labor and the Government agencies in charge of building and construction work essential to th prosecution of the war. It was agreed at this time to stabilize wage on Federal projects as of July 1, 1942, for the duration of the war, a rates in effect under collective bargaining agreements. Wage ad justments were to be permitted on the recommendation of a wage adjustment board, if the wages (a) were fixed at a time so long before July 1, 1942, as to be out of line with the general wages prevailing; (b) were applicable in a locality where changing conditions in the building construction industry require a revision of wage rates; or (c) do not sufficiently take into account any abnormal change in conditions.

Immediately following the agreement, the administrative order establishing a Wage Adjustment Board for the Building Construction Industry was issued by the Secretary of Labor, with the President's approval. The Board was composed of two officials of the Labor Department, three representatives of Federal contracting agencies and three representatives of labor organizations in the building and construction industry.

When the Emergency Price Control Act of October 2, 1942 was passed and Executive Order 9250, October 3, 1942, was issued provid-ng for the stabilization of the national economy, responsibility for over-all wage stabilization and for approval of wage changes was placed in the National War Labor Board. The Wage Adjustment Board, however, was to continue to function under the War Labor Board as a distinct part of the stabilization program. Moreover, on October 13, 1943 all non-Federal as well as Federal construction wage ases were turned over to the Wage Adjustment Board, and the oard was reconstituted into a tripartite body with three members rom the public, three from labor, and three from industry.

According to General Order No. 13 setting up the tripartite Board, he Wage Adjustment Board would be subject both to the provisions f the Wage Stabilization Agreement of May 22, 1942, and to the re-uirements of the National Wage Stabilization Policy. It was stated rther that (a) "brackets of sound and tested going rates" could not e used in appraising adjustments in the rates of workers on building onstruction projects; (b) the benefits of the "Little Steel" formula ould be available to employees in the construction industry; (c) the age Adjustment Board may approve adjustments necessary to rrect substandards of living; and (d) all adjustments not permis-ble in the above principles but which, in the opinion of the Wage djustment Board, are necessary to the successful prosecution of the r, should be submitted for approval to the National War Labor oard and the Economic Stabilization Director.

The fundamental procedures and policies for adjusting construction ge rates remained substantially unchanged up to November 9, 1946, hough the principles and procedures by which wages in other dustries were adjusted changed materially right after VJ-day. hereas during the war, all wage adjustments were subject to direct control, Executive Order No. 9599, issued August 18, 1945, permitted all but construction employers to make wage increases of any amount without governmental approval, provided the increases were not used as a basis for price increases or increase in the cost of goods or services furnished the United States under procurement agency contracts. All decreases continued under control. By Executive Order No. 9651 (October 30, 1945) the Price Administrator was authorized to take even unapproved wage or salary increases into account for price purposes, after such increases had been in effect for at least 6 months. Wage adjustments which would be used immediately as bases for applying for price relief remained subject to control under certain regulations and standards set forth by the President or by the Stabilization Administrator. The National War Labor Board was succeeded, on its termination December 31, 1945, by the National Wage Stabilization Board, which took over all of the duties and responsibilities of the NWLB, including those relating to the Wage Adjustment Board.

The question was inevitably posed as to why it was necessary to obtain approval for all wage-rate increases in construction when other industries had been partially relieved of this necessity. The answer was that Government wage policy was construed actually to be the same for all industries, but that in adapting the new stabilization policy to construction, the conclusion was reached by Government stabilization officials that any wage increase in construction would result in an actual or potential price increase. It was, therefore, concluded that control over all wage changes should remain in force. Labor costs are of course a large part of construction costs and it was reasoned that job estimates, which invariably reflect prevailing wage rates, would rise as wage rates rose.

In applying the principles of stabilization to the building industry, the Wage Adjustment Board steered a moderate course. Until general wage controls were relaxed after VJ-day, wage increases on construction were kept within the bounds of the Little Steel formula—15 percent of the January 1, 1941 wage rate—except in rare cases vitally affecting war production, and such cases were subject to review and approval of the Director of Economic Stabilization. After August 1945, the principal criterion applied in determining the validity of construction wage increases was the equalizing of intercraft and interarea inequities. Adjustments were also authorized to eliminate substandard wages and to compensate for the rise in cos of living.

Between expiration of the Stabilization Act, June 30, 1946, and approval of the Price-Control Extension Act on July 25, 1946, wage as well as prices were not legally subject to Government control

During this interim period, while awaiting congressional action and Presidential approval of a stabilization policy, the Wage Adjustment Board recommended a hold-the-line policy. As soon as the Price-Control Extension Act was passed, the Board issued a statement requiring a roll-back of construction wages to the June 30, 1946, level, making August 10, 1946, the deadline for the roll-back, and suggesting that applications for increases which had been made during the interim period be filed immediately. The result was an avalanche of an average of 225 cases a week during the 6 weeks ending September 6, 1946. The weekly number of cases received in the Board was even greater, however, during the spring period, when new contracts are usually negotiated, so that the number stood at well over 250 a week during late April and the first half of May. In October, cases were received at the rate of 100 to 175 a week.

The requests made of the Board were, in most instances, for area rates. Authorizations for adjustment by the Wage Adjustment Board were generally of two types. First, an individual adjustment in response to an application, affecting only those employers signatory to the application, and, second, an adjustment of an area rate which has general application and may be adopted by any contractor in the area, regardless of his previous wage rate history. The policy reflected in the latter type of authorization was of comparatively recent origin, having been adopted by the Board in May 1946.

All wage and salary controls, including those in building construc-ion, were removed on November 9, 1946, by Executive Order 9801 and the Wage Adjustment Board has since ceased operations.

Union Scales of Wages and Hours by Cities and Trades

Table 13 lists the union rates of wages per hour and hours per week n effect on July 1, 1946, and July 1, 1945, for each building trade for which there was an effective union scale in each of the 75 cities included n the survey.

Where two or more union rates for the same occupation in the same ity were shown, this was due to the presence of more than one union, ach having different scales or to the fact that a particular union had several agreements with different employers. In some cases both of hese situations were found simultaneously. Where more than one nion rate was effective all were listed, and the letters, A, B, C, etc., ere used to designate the different quotations. The sequence of e letters does not indicate the relative importance of the quotations unions so designated.

Table 14 gives the rate changes between July 1, 1946, and January , 1947.

Letter of Transmittal

UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS,
Washington, D. C., June 5, 1947

The SECRETARY OF LABOR:

I have the honor to transmit herewith the annual report on wages and hours of union motortruck drivers and helpers in 75 cities, as of July 1, 1946.

This report was prepared in the Bureau's Wage Analysis Branch by James P. Corkery, under the direction of Donald H. Gerrish.

EWAN CLAGUE, *Commissioner.*

Hon. L. B. SCHWELLENBACH,

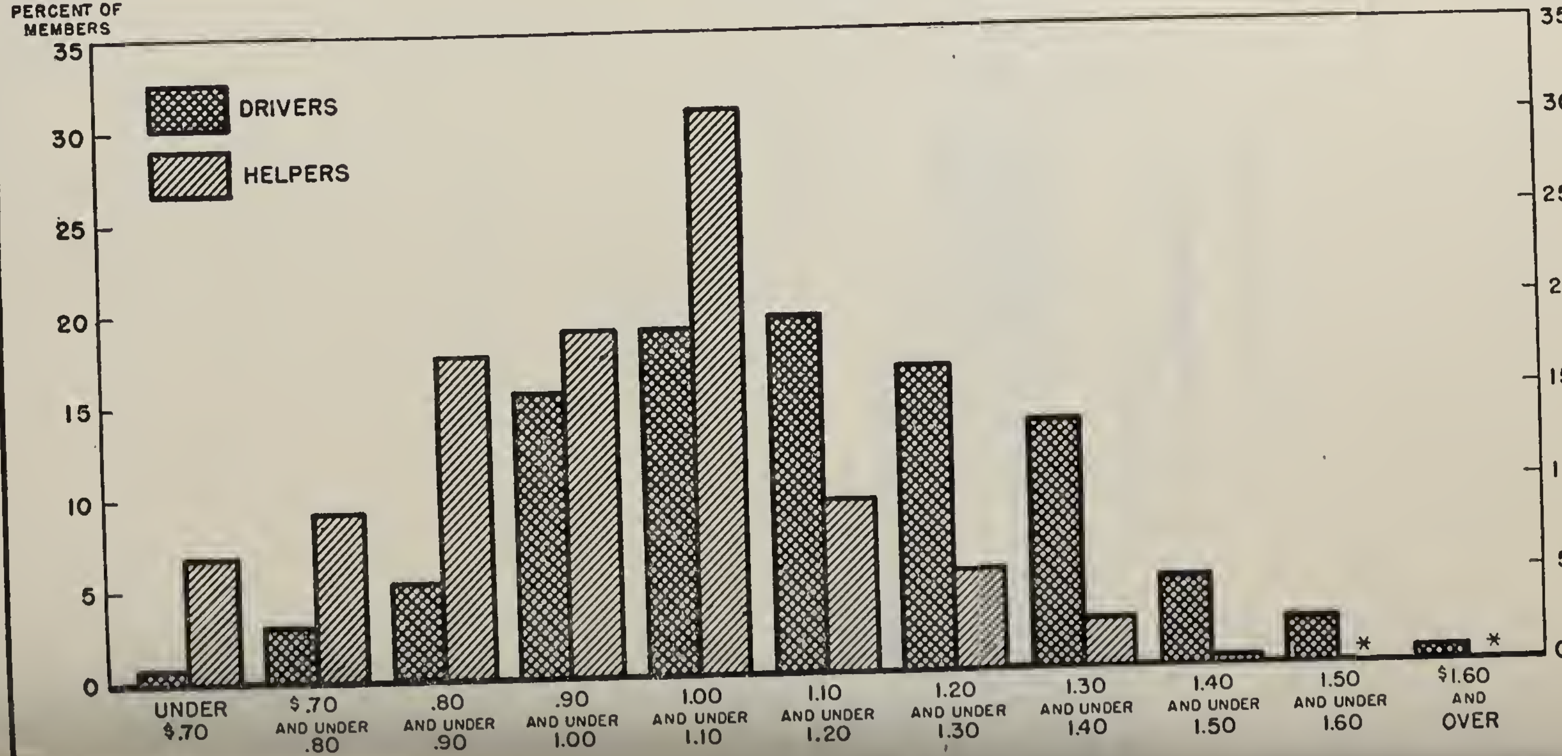
DISTRIBUTION OF UNION MOTORTRUCK DRIVERS AND HELPERS ACCORDING TO HOURLY RATES

JULY 1, 1946



BUREAU OF LABOR STATISTICS

*LESS THAN .05 OF ONE PERCENT

lletin No. 911 of the
ited States Bureau of Labor Statistics

Union Wages and Hours of Motortruck Drivers and Helpers, July 1, 1946

Summary

Jnion motortruck drivers in 75 cities averaged $1.13 an hour
July 1, 1946, an increase of 11 percent in the union wage scale
r July 1, 1945. Helpers who rode on the trucks averaged 96
ts an hour, an advance of about 12 percent. About 9 of every
drivers received an increase, as contrasted with only about 3
of every 10 during the previous year. The rates for over four-
hs of the helpers also advanced between 1945 and 1946. Rates
ween $1.00 and $1.20 were paid to almost 40 percent of the
vers. Of the 75 cities studied, Seattle had the highest average
.36), Jackson ($0.76) and San Antonio ($0.79) had the lowest.
traight-time weekly hours on July 1, 1946, averaged 44.7 for
vers and 43.8 for helpers. For drivers this represents an aver-
reduction of 2 percent since 1945. Forty hours constituted the
ight-time workweek for almost 45 percent of the drivers and
r half of all helpers surveyed.

ime and a half was the usual overtime rate for all hours worked
xcess of those stipulated in the union agreement. Double time,
ime and a half was typical for all Sunday work or work on the
consecutive day.

bout 8 of every 10 truck drivers and helpers worked under
eements providing for paid vacations.

Scope and Method of Study

his study is one of a series of annual surveys of union wage
es in selected trades in 75 cities of the United States.[1] Although
n scales for a few driver classifications are available as far
as 1907, the index series showing the general trend of union
es dates back only to 1936. The limited data available for prior

---

e data for this study were obtained by field representatives, working from the regional
of the Bureau, through personal interviews with union officials and employers in each
he report covered 218,579 motortruck drivers and 31,465 helpers who rode on the trucks.

years in this industry were insufficient to warrant the compilation of an index series.

All of the figures in this report were based on effective union scales, a union scale being a minimum wage rate and maximum schedule of hours agreed upon through collective bargaining between employers or their bargaining associations and labor unions.[2]

All truck driving in each city is treated as one trade, separation being made only between drivers and helpers.

The survey primarily covered city trucking. Rates for drivers operating trucks on long-distance runs from terminals located in the cities surveyed were included when payment was on an hourly rather than a mileage basis.[3]

Bakery, beer, laundry, and milk drivers were generally paid minimum weekly guarantees plus commissions based on the volume of individual sales. Over-the-road or long distance drivers were usually compensated on a trip or mileage basis. Since such quotations based on commission, trip, or mileage rates could no be converted to an hourly basis, they have been excluded from the computations.

Trend of Union Wage Rates and Weekly Hours [4]

Wage rates.—Union wage rates for truck drivers advance slightly more than 11 percent between July 1, 1945 and July 1 1946. Most of the increase took place after VJ-day and represente the largest advance recorded in any of the 10 years for whic comparable data are available. The largest previous increases too place during the period between the beginning of World War I and the effective date of Federal wage stabilization orders. Thes increases amounted to 6.8 percent between 1941 and 1942 and 5. percent between 1942 and 1943. Rates for drivers' helpers show slightly greater percentage increase.

---

[2] Some union members may receive rates in excess of the minimum agreed upon because seniority, special skills, or other personal reasons. These rates were not considered in preparation of this report.

[3] No Nation-wide combination has been made of the scales which prevail for differ commodities (such as coal, ice, building materials, beer, general commodities, baggage expr heavy freight, and other items) or for different sizes of trucks. Local rate differentials h developed over a period of years through local collective bargaining and there is, as a res considerable variation from city to city. For example, building material drivers in one may have higher rates than drivers who handle general commodities, while in another the reverse may be true.

[4] In computing the index series (1939 = 100) which indicates the trend of wage rates, annual percentage change from year to year is derived from aggregates of union quotati for identical classifications in two successive years. The membership weights in both of aggregates used for each year-to-year comparison are those reported for the second year. obtain the index for the current year, the total of the current aggregates is divided by previous year's aggregates and the ratio thus obtained is multiplied by the previous ye index numbers. The indexes are computed on this basis in order to minimize the effec changes in union membership which might obscure the real changes in wages.

Weekly hours.—Average straight-time weekly hours[5] for truck rivers dropped 2 percent during the period from July 1, 1945 to uly 1, 1946. This reflected reductions in straight-time hours from 8 or 44 to 40 per week to conform with the hours generally ef- ective in industry. Straight-time hours for drivers have been ropping steadily since 1937 (except for an insignificant increase etween 1941 and 1942) the first year for which comparable data re available.

TABLE 1.—*Indexes of hourly wage rates and weekly hours for union motortruck drivers and helpers, 1936–46*

[1939 = 100]

nformation not computed separately in 1936.

stribution of Union Members by Hourly Wage Rates, 1946

Organized motortruck drivers averaged $1.13 an hour in the cities surveyed on July 1, 1946. Helpers who rode on the trucks eraged 96 cents an hour. Almost two-fifths of all drivers had es ranging from $1.00 to $1.20, and an additional 37 percent re paid in excess of $1.20. The remaining 25 percent received s than $1.00, with only 6 percent receiving less than 85 cents. nong the wide range of rates reported, the highest was a rate $2.00 an hour covering a few dump-truck drivers in St. Louis l drivers of dump trucks of over 20-yards capacity in Seattle. e lowest scale (50 cents an hour) was for ½-ton retail grocery cks in Chicago. The most frequently quoted rates in order of oortance were $1.00, 90 cents, 95 cents, $1.15, and $1.25.

)ver 30 percent of all helpers received rates between $1.00 and 10 on July 1, 1946, as compared with only about 13 percent eiving these rates on July 1, 1945.

bout 10 percent of all helpers received between $1.10 and 20, while only 8 percent exceeded $1.20. The highest individual

---

eekly hours as discussed here refer to the number of hours that may be worked per before overtime rates become effective.

helper scale reported ($1.47) covered heavy hauling freight helpers in Minneapolis and winch truck operators' helpers in St. Paul. The lowest rate reported (50 cents) included quotations for helpers on ice trucks in Kansas City, milk drivers' helpers in Providence and helpers on beer transport trucks in Tampa.

TABLE 2.—*Percentage distribution of union motortruck drivers and helpers by hourly wage rates, July 1, 1946*

Union scale	Drivers and helpers	Drivers	Helpers

Weekly Hours[6]

Straight-time weekly hours for union truck drivers in 75 cities averaged 44.7 on July 1, 1946. The average was somewhat less (43.8 hours) for helpers. Forty hours constituted the straight-time workweek for almost 45 percent of the drivers and over half of all helpers surveyed. Many of the members had a 48-hour week (27.5 percent of the drivers and 29.4 percent of the helpers) Approximately 10 percent of both drivers and helpers worke under contracts providing for a 44-hour week. Although about 1 percent of the drivers had a workweek in excess of 48 hours, onl 7 percent of the helpers were reported in this category. Thirty-five hours was the shortest workweek reported and 60 hours th longest. For the most part, workers on the maximum hour schedule were engaged in operating long-distance or over-the-roa trucks under the regulations of the Interstate Commerce Commission.

A considerable number of the union drivers and helpers covere in the present study were employed by establishments engage entirely in intrastate commerce. Consequently they were not sub ject to the provisions of the Fair Labor Standards Act, whic requires premium pay at the rate of time and one half for hours worked in excess of 40 per week. Moreover, trucking oper

---

[6] See footnote 5.

ions involving interstate commerce are specifically exempted
rom the provisions of this Act. The Interstate Commerce Com-
aission, however, exercises jurisdiction over trucking operations
n interstate commerce with respect to conditions affecting the
afety of operations. The Commission has ruled that employers of
rivers operating vehicles in interstate commerce may not require
heir drivers to remain on duty more than 60 hours in a period
f 168 consecutive hours. Various exceptions are allowed regarding
aily and weekly hours.[7]

ABLE 3.—*Percentage distribution of union motortruck drivers and helpers by straight-time hours per week, July 1, 1946*

Hours per week	Percent of union members		
	Drivers and helpers	Drivers	Helpers

[1] Less than .05 of 1 percent.

Changes in Wage Rates and Hours, From 1945 to 1946

Wage rates.—About 9 of every 10 truck drivers studied ob-
ined wage increases between July 1, 1945 and July 1, 1946. The
ates for over four-fifths of the helpers also advanced during this
ame period. The amount of increase for a majority of the drivers
nged from 5 to 20 percent, with a fifth receiving 10 to 15 percent
creases and an additional fifth getting between 15 and 20 per-
ent. The rates for approximately 1 driver in 10 advanced less
an 5 percent, while gains of as much as 25 percent were limited
1 of every 20 drivers. About one-fifth of the helpers had rate
lvances between 5 and 10 percent and an additional fifth received
creases of at least 10 but less than 15 percent. Gains of 25 per-
ent or better involved about 1 helper in 10, while only a few of
e helpers had increases of less than 5 percent.

An essential difference between the hour regulations of the Interstate Commerce Com-
ssion and of the Fair Labor Standards Act should be noted. Whereas the Interstate Com-
rce Commission regulations specify maximum hours which may not be exceeded, the
gulations under the Fair Labor Standards Act merely specify the maximum hours that
y be worked at straight-time rates, and do not limit the total number of hours that may
worked, provided time and a half is paid for all hours in excess of the specified week. (See
erstate Commerce Commission: Motor Carrier Safety Regulations Revised).

Weekly hours.—Between July 1, 1945 and July 1, 1946, about 14 percent of the union motortruck drivers and 17 percent of the helpers benefited by a reduction in their straight-time workweek. Increases in straight-time hours during this period were comparatively minor, affecting only about 1 percent of all drivers and helpers. A great majority (85 percent) of all union workers covered in the industry reported no change in hours since the previous study.

TABLE 4.—*Extent of increases in wage rates of motortruck drivers and helpers and percent of members affected, July 1, 1946*

Occupation	Percent of members whose wage rates were—		Percent of total members affected by increase of—							
	Not changed	Increased	Less than 5 percent	5 and under 10 percent	10 and under 15 percent	15 and under 20 percent	20 and under 25 percent	25 and under 30 percent	30 and under 35 percent	35 percen and over
Truck drivers and helpers	14.2	85.8	9.9	17.3	22 1	21.6	9.3	3.1	1.4	1 1
Drivers	14.0	86.0	10.5	16.8	22.2	22.8	8.9	2 8	1.2	
Helpers	16.0	84.0	5.7	20.8	20.3	14.1	11.9	5.3	2.6	3 3

Average Wage Rates and Changes by City [8]

Average wage rates.—Union motortruck drivers in Seattle hac the highest average ($1.36) of any of the 75 cities surveyed as o July 1, 1946. San Francisco ($1.32) was the next highest, followe closely by New York ($1.31). The averages for 9 additiona cities were in excess of the $1.13 an hour average for all citie combined (table 5). Twenty other cities had averages in exces of $1.00 per hour, while the averages for 21 ranged between 9 cents and $1.00. Of the remaining cities, 18 had averages betwee 80 and 90 cents, while Jackson, Miss. ($0.76) and San Antoni ($0.79) had the lowest of the 75 cities studied.

Percentage changes.—All of the 75 cities studied registered in creases in basic rates between July 1, 1945 and July 1, 1946. Th largest relative increases were recorded for Nashville (22 percer or about 15 cents per hour); Oklahoma City (21 percent or 1 cents); Jackson, Miss., and Birmingham (20 percent or 18 ar 13 cents, respectively).

The large increase in hourly rates for Nashville reflected pr marily an increase in rates for local freight delivery drivers fro 62 to 80 cents an hour, while in Oklahoma City rates for transf storage drivers advanced from 60 to 75 cents. In Birmingha city pick-up and delivery drivers' rates were raised from 65 ce o 80 cents. In Jackson, Miss., rates for railway express drivers ncreased from 92 cents to $1.10.

---

[8] The average rate shown for each city is a composite of all rates quoted for each diffe t type of truck driver weighted by the number of union members covered by each rate.

Seventeen other cities had increases of at least 15 percent, while he averages for 23 additional cities exceeded the 11 percent averge increase for all cities combined. The lowest average increases ere indicated for Portland, Maine (3 percent or 2½ cents) and Ianchester, N. H. and Wichita (4 percent or about 3 cents an our).

Regional Differences in Wage Rates

Average union wage rates (table 6), were higher in the North l Pacific region than in the South and Southwest, except for all cities. Differences in favor of the North and Pacific region re 26 cents in cities of 250,000—500,000 population and 12 ts among cities of 100,000—250,000. The difference in favor the South and Southwest in the smallest size (40,000—100,000) es amounted to 9 cents.

Helpers' averages for all city size groups were higher in the North and Pacific region than in the South and Southwest, the advantage amounting to 25 cents for group III cities, 22 cents for group IV cities, and only 1 cent for group V cities (see table 6).

TABLE 6.—*Average union wage rates for motortruck drivers and helpers, by region and population group, July 1, 1946*

Occupation	Cities in population group [1]—										
	I [2]	II [2]	III			IV			V		
	North and Pacific	North and Pacific	All cities	North and Pacific	South and South-west	All cities	North and Pacific	South and South-west	All cities	North and Pacific	South and South-west

[2] No city of this size in the South or Southwest.

Overtime and Sunday Rates

Practically all of the drivers (93 percent) received pay at the rate of time and a half for all hours worked beyond those stipulated in the union contract (table 7). Most of the others worked indefinite hours without premium overtime rates. Double time rates were paid to a very few, and overtime was prohibited in a negligible number of cases.

The situation was somewhat different with regard to Sunda work. About half of the drivers received double pay if they wer required to work on Sunday or for the seventh consecutive da Over a third received time and a half, but for 14 percent no speci rate was specified for Sunday work. Sunday work was prohibite for only a few drivers.

TABLE 7.—*Overtime and Sunday rates for truck drivers and helpers provid in union agreements, effective July 1, 1946*

Item	Percent of members affected—			Item	Percent of members affected—		
	Drivers and helpers	Drivers	Helpers		Drivers and helpers	Drivers	Help
By overtime rate:				By Sunday rate:			
No overtime rate specified	5.4	3.6	5.1	No Sunday rate specified	13.7	15.3	[illegible]

Paid Vacations for Truck Drivers

More than 9 out of every 10 truck drivers and helpers included
ı the study worked under collective bargaining contracts that
rovided for vacations with pay (table 8). More than a third
eceived a vacation of 1 week after 1 year of service with an
dditional week after 5 years. Over a fourth of the drivers and
elpers worked under agreements calling for a week of paid vaca-
on after 1 year of service without any provision for additional
ıcation time per year regardless of length of service. Nearly 8
ercent of the workers were given paid vacations of 2 weeks if
nployed for 1 year. The others, entitled to this benefit, received
ıid vacations under various plans such as 1 week after 1 year
ıd 2 weeks after 2 years of service; 1 week after 1 year and 2
eeks after 3 years, etc.

TABLE 8.—*Percentage distribution of truck drivers and helpers according to vacation with pay provisions*

1 week after 6 months, and 2 weeks after 1 year	.2
1 week after 1 year, 2 weeks after 5 years, and 3 weeks after 15 years	.1
Other than any of above listed	10.4
No paid vacation	6.0
No information	1.0

Post-Survey Rate Changes

Available information, though limited, indicates that many rate
ɛreases have become effective for the trucking industry since
ly 1, 1946. Gains of 25 cents an hour were reported for drivers
oil trucks in St. Louis, coal drivers in Peoria, and biscuit driv-
in Baltimore. More substantial advances were reported for
nored car drivers in New York, general freight and soda bev-
ıge drivers in Chicago, provision drivers in Los Angeles, and
rist drivers in St. Paul. In New York, truck drivers engaged
general intracity delivery service received an increase of $7.40
week coupled with a reduction in the workweek from 44 hours
40, resulting in an advance in basic hourly rates of 30 cents.
edo coal drivers and helpers, Milwaukee furniture drivers,

Portland, Oreg. wholesale grocery trailer drivers, Denver fish drivers, Detroit petroleum drivers, and Duluth wholesale-drug drivers registered gains amounting to at least 20 cents an hour. Among those receiving increases between 15 and 20 cents, were building material drivers in Jacksonville, Los Angeles, and Louisville; coal and ice drivers in Dayton and Grand Rapids; parcel and pick-up drivers in Portland, Oreg. and Denver; laundry teamsters in Detroit and Peoria; produce drivers in Los Angeles; and furniture and piano movers in Chicago. Increases of at least 10 cents were reported for Denver and Jacksonville beer drivers; Binghamton furniture movers; Charlotte grocery, meat, and produce drivers; Los Angeles bakery and ice drivers; Pittsburgh and Louisville creamery teamsters; Duluth plate glass drivers; Chicago excavating drivers; and Minneapolis linen supply drivers. Smaller gains were reported for special commodity teamsters in 13 cities.

Union Scales of Wages and Hours, by City

The rates of wages per hour and hours per week on July 1, 1946 and July 1, 1945, for each classification of union motortruck driver and helpers in selected cities are shown in table 9.

In a number of cities there are two or more union rates for th same type of truck driving. This may be due to the existence o two or more unions having different scales, to a single union havin different agreements with different employers for various reason or to both these situations. Where more than one union rate is i effect for the same type of trucking, rates are listed in the follow ing table with the designations "Agreement A," "B," "C," et The designations "Rate A," "B," "C," etc., are used wheneve two or more otherwise unclassified rates appear in the same agre ment. The sequence of the alphabetical designations is in no wa intended to indicate the relative importance of the agreemen or rates.

When a union agreement guarantees a minimum workwe which includes a limited number of hours paid for at an overti rate (e.g., a guaranteed workweek of 48 hours, 40 of which a at straight time and 8 at time and a half), the hours and t rates shown in table 9 do not reflect the premium payment. Sin previous reports reflected the total guaranteed hours and overti payment, the 1945 rates will not in all cases be consistent wi those reported in Bulletin No. 874.

Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., June 30, 1947.

The Secretary of Labor:

I have the honor to transmit herewith a report covering union wages a
hours in the printing trades, as of July 1, 1946.

This report was prepared in the Bureau's Wage Analysis Branch by Anne
V. Simi, James P. Corkery, and Herbert M. Abowitz, under the direction
Donald H. Gerrish.

Ewan Clague, *Commissioner*

Hon. L. B. Schwellenbach,
Secretary of Labor.

UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

Bulletin No. 912 of the
United States Bureau of Labor Statistics

Union Wages and Hours in the Printing Trades, July 1, 1946

Summary

Union wage rates for all printing trades workers averaged $1.58 an hour on July 1, 1946. Practically all of the organized tradesmen had received substantial wage increases since VJ-day, averaging 17 percent. The average for day shift newspaper workers on July 1, 1946 ($1.69) was 13 percent higher than that for day shift book and job workers ($1.49). Photoengravers recorded the highest averages for both branches of the industry ($1.97 in book and job shops and $2.06 an hour on newspapers). Bindery women had the lowest average in the commercial branch (81 cents) and mailers had the lowest newspaper average ($1.47).

The straight-time workweek averaged 38.3 hours for book and ob workers and 37.5 hours for newspaper workers. There was a ubstantial reduction in straight-time weekly hours during the ear for the job workers, and a slight reduction for newspaper workers.

Almost all printing trades workers received time and a half as he initial overtime rate. Double time rates were provided for 93 ercent of the members in the book and job branch for work perormed on Sunday or the seventh consecutive day, and for 51 perent of the newspaper workers for nonscheduled work on those ays.

Over half of all the printing trades workers studied were covered by union agreements that called for 2 weeks of paid vacation fter 1 year of service.

Introduction

This study was based on union wage scales effective July 1, 46, in 75 cities (ranging in size from 40,000 to over 1,000,000) d covered 11 book and job and 8 newspaper occupations.[1] The union scales studied were the minimum wage rates and maximum number of hours agreed upon through collective bargaining between employers or their associations and trade-unions. Rates in excess of the agreed minima are paid to some workers by reason of seniority, special skills, or for personal or other reasons. Such rates were not used in the preparation of this report. The various averages presented are based on effective union scales weighted by the number of members working at each specific wage rate. Collective bargaining contracts are on file covering over 88 percent of the workers included in this study.

---

[1] Almost 2,700 rate quotations covering 71,533 union members in the book and job branch of industry and 34,298 members in the newspaper branch were collected by field representatives king out of the Bureau's regional offices. Bureau estimates of employment in the printing ustry on the survey date indicate 130,100 workers in the newspaper branch and 190,700 kers in the commercial branch.

Union Hourly Wage Rates

TREND OF UNION WAGE RATES

Indicative of the upward wage trend since VJ-day was the 17 percent increase (about 23 cents an hour) in the average rates of union printing trades workers in 75 cities between July 1, 1945, and July 1, 1946. The percentage increase for newspaper workers was just slightly less than that for book and job (16 compared to 18 percent). However, in money terms, average rates of union newspaper workers improved by approximately 25 cents an hour and commercial workers 22 cents.

The wage rate index for all printing trades workers rose more during the 1945–46 period than in any other single year since 1919–20, when it showed an increase of over 28 percent or about 18 cents an hour. Between 1918 and 1919, a period after World War I that may be compared with the current period, rates fo printing trades workers increased about 22 percent or 11 cents an hour.

TREND IN INDIVIDUAL TRADES

During the period between July 1, 1945, and July 1, 1946, th wage rate index of every trade included in the survey rose considerably. The greatest increases registered (22 percent) wer reported for the bindery women in the book and job branch an for mailers in the newspaper branch (14 cents and 27 cents respectively). The smallest percentage increase reported (14 percent, 23 cents), covered the electrotypers in the book and jo branch.

Union wage scales for individual trades in both branches the industry have shown a consistent upward trend since th establishment of the index series, with the exception of a slig drop in the early 1920's and a serious dip between 1932 and 193 Bindery women and mailers, who had the lowest base rates, show

---

[1] Includes pressmen-in-charge.

the highest percentage increase since 1939 (46 percent or 25 cents for bindery women, 40 percent or 41 cents for book and job mailers and 51 percent or 50 cents for newspaper mailers). Photoengravers, who had the highest base rates, showed the smallest percentage increases since 1939 (27 percent representing 42 cents in the book and job and 26 percent or 43 cents in the newspaper branch).

CHANGES IN UNION WAGE RATES BETWEEN 1945 AND 1946

Practically all of the organized printing trades workers—book and job 99 percent, newspapers 96 percent—received wage increases during the year. The largest single bloc of members (over a third) registered gains of from 15 to 20 percent. About one-fifth of the workers received wage increases of 10 to 15 percent and another fifth 20 to 25 percent. In sharp contrast, the preceding study of the printing trades (July 1, 1945) revealed that only 33 percent of the book and job workers and 39 percent of the newspaper workers received increases during the 1944–45 period, with out few recording basic rate improvement of as much as 10 ercent.

In the book and job branch, the trades reporting the largest nembership proportions benefiting by increases of 25 percent nd over were those with the lower general wage averages: bindery women (49.4 percent of the members), mailers (30.7 percent), ress assistants and feeders (28.3 percent). At least three out f every four bindery women, bookbinders, hand compositors, ma- hine operators, mailers, press assistants and feeders, and platen ressmen registered rate advances of 15 percent or better. Con- ersely, trades with averages consistently in the higher levels, uch as photoengravers, electrotypers, machine tenders, and cylin- er pressmen revealed sizable concentrations of membership bene- ting by gains of less than 15 percent.

About three-fourths of the newspaper tradesmen reporting ains obtained raises of 10 to 25 percent, with almost equal por- ons falling into each 5 percent interval of the range. Day and ght shift pressmen-in-charge and mailers, and day shift press- en and machine tenders indicated the largest proportion of mem- ership with increases amounting to 25 percent or more. More an one of every three day shift hand compositors and machine erators and day and night shift machine tenders recorded rate tterments of 10 to 15 percent. Similar proportions of night shift nd compositors, machine operators, pressmen, pressmen-in- arge and day and night shift photoengravers and stereotypers

TABLE 3.—*Extent of changes in union wage rates and percent of members affected by increases, July 1, 1945, to July 1, 1946*

registered gains of 15 to 20 percent. The most substantial membership group recording increases of 20 to 25 percent were mailers, pressmen, and day shift photoengravers. Newspaper photoengravers reported the highest proportion of members with no change in wage rates from that of last July 1 (day shift 11.1 percent, night 10.3).

POST SURVEY RATE CHANGES

Limited data available indicate that many rate increases hav become effective in the printing industry since July 1, 1946. O particular significance in the book and job branch were gains o about 40 cents an hour for typographical workers in New York and Chicago, both important centers of the industry. Other increases ranging from 10 to 67 cents an hour were reported for typographical workers in 29 cities. Reports of increases up to 26 cents an hour for photoengravers were received in 4 cities. Electrotypers in Springfield were reported to have advanced by about 33 cents and from 5 to 18 cents in three other cities. In Chicago, pressmen and press assistants were reported to have received a 26-cent raise. Increases up to 39 cents an hour were indicated in several cities for bookbinders and mailers.

In the newspaper branch typographers were reported to have advanced by over 40 cents an hour in Rochester, and by at least 30 cents in Baltimore, Boston, Buffalo, Columbus, Dallas, Minneapolis, South Bend, Washington, and Wichita. Rates for pressmen in Toledo and Indianapolis went up 44 and 32 cents an hour, respectively. Dallas stereotypers were recipients of a 31 cent increase, and higher scales were also reported for this trade in 4 other cities. Increases of varying amounts were also indicated in several cities for photoengravers and mailers.

AVERAGE HOURLY WAGE RATES, JULY 1, 1946

Union printing trades workers averaged $1.58 an hour in the
75 cities surveyed on July 1, 1946. The average for day shift
iewspaper workers ($1.69) was about 13 percent higher than the
verage for book and job workers ($1.49). Average rates for
ight shift newspaper workers ($1.87) were about 10 percent
igher than for the day shift ($1.69). Rates for night shift book
nd job workers were not tabulated, but workers on regular night
hift generally received about $5 more per 40- or 37½-hour week
ian day shift workers.

Over half of all printing trades workers had rates ranging from
1.50 to $2. In the book and job branch, more than a third of all
embers received from $1.40 to $1.70 and a fifth had rates be-
veen $1.80 and $2. In the newspaper branch, a fourth received
etween $1.50 and $1.70 and at least another fourth earned be-
veen $1.70 and $1.90. Only 7 percent of the book and job work-
s had rates of $2 or more, as compared with 26 percent in the
wspaper branch.

Averages for individual trades in the commercial branch varied
om $0.81 for bindery women to $1.97 for photoengravers. About
lf of all bindery women received less than 80 cents and only a
gligible proportion received over $1.10. On the other hand, none
the photoengravers received less than $1.30 and a substantial

TABLE 4.—*Percentage distribution of union members in the printing trades, by hourly rates, July 1, 1946*

number earned over $2. Electrotypers with the second highest average ($1.87) in the book and job branch reported over 50 percent of their membership with rates of $2.10 and over. The lowest individual rate reported (40 cents an hour) was for platen press assistants in San Antonio and the highest ($2.37) was for the first position on a 10-color perfecting process press in Chicago.

In the newspaper branch, photoengravers also had the highest average ($2.06) while mailers had the lowest ($1.47). One-quarter of the machine tenders (machinists) in the day group had rates in excess of $2 and in the night group more than two-fifths had rates of $2.10 and over. Other trades with substantial proportions of their night shift membership receiving rates of $2.00 or more were hand compositors (45.8 percent), machine operators (46.3), photoengravers (76.2), pressmen (34.8), pressmen-in-charge (60.3), and stereotypers (32.6). The lowest individual rate found in the newspaper branch (70 cents) was for group A bench mailers in Portland, Maine. The highest ($3.11) was received by hand compositors and machine operators on the night shift of Hebrew text newspapers in New York City.

NIGHT RATE DIFFERENTIALS IN NEWSPAPER TRADES

Union agreements for the newspaper printing trades in the 75 cities surveyed provided an average differential of 14 cents an hour in favor of night workers.[2] Pressmen-in-charge indicated the highest average differential (20.6 cents an hour) while the lowest (about 11 cents) was reported for members of the typographical union.

Among the individual trades, all except typographical machine tenders (machinists), mailers, and photoengravers had some proportion of their members with differentials of 30 cents or more an hour. Journeymen pressmen had 23 percent and pressmen-in-charge 17.3 percent in this category. The greatest difference between day and night scales (77.8 cents) was found in the Hebrew publishing field in New York City where hand compositors and machine operators had the same daily rate for a night shift of 4½ hours and a day shift of 6 hours. Night rates for stereotypers in Newark were 52 cents an hour above day rates and in New York City 46 cents, resulting from shorter hours worked for the same daily scale. In Chicago, stereotypers on foreign language dailies had a night differential of 42.6 cents due to a shorter work week plus higher night scales. The lowest differential between day and night work (2 cents) was reported for stereotypers in Mobile

---

[2] These higher rates, however, do not necessarily mean that average earnings of the nig shift workers were greater since this differential is often the result of night workers receivi the same daily or weekly scale as day workers, but for fewer hours of work.

DIFFERENCES IN WAGE RATES BY CITY AND REGION

Average wage rates of union printing-trades workers were progressively higher according to size of city; in almost all cases highest averages being recorded for the largest city size groups. In the book and job branch, a differential of almost 28 cents an hour separated cities of over 1,000,000 population from cities of 500,000–1,000,000, whereas in the newspaper branch the largest differential (16.5 cents) existed between cities of 250,000–500,000 and cities with 100,000–250,000 population. Chicago with an average of $1.72 in the book and job branch and New York with an average of $2.06 in the newspaper branch led all cities in group I. In the other four city size groups in the book and job branch, San Francisco ($1.53), Seattle ($1.65), Salt Lake City ($1.50), and

---

[1] The averages in the book and job table include rates for the semiskilled—bindery women and press assistants and feeders—as well as the highly skilled journeymen composing room and pressroom workers and others. If there are large numbers of the semiskilled workers organized in one city as compared to another, the average rate for the city with the high degree of organization among semiskilled workers will tend to be lower in this table than the average for a city where only the skilled workers are organized.

[2] Includes Rock Island and Moline, Ill. and Davenport, Iowa.

El Paso ($1.48) had the highest averages. In the newspaper branch, Cleveland with an average of $1.90 reported the highest wage rates among group II cities, Cincinnati ($1.85) in group III, Jacksonville ($1.70) in group IV, and Butte ($1.54) in group V cities.

As in previous years, with the exception of group V cities, rates for union printing-trades workers in the North and Pacific regio were generally higher than in the South and Southwest region This was true for the book and job branch in 25 out of 30 possible comparisons and for the newspaper branch in 36 out of 4 cases.

[3] Insufficient quotations to compute an average.

PERCENT OF CHANGE BY CITIES[3]

Jackson, Miss., reported the largest percentage wage increase (37.8) for all printing-trades workers. The advance in rates was from 95 cents to $1.25 for hand compositors and machine operators in the book and job branch and from 95 cents to $1.35 for he same trades in the newspaper branch. The smallest percentage increase was that recorded for Duluth (6.4 percent) repre-
enting an advance in the city average of 8 cents.

ncludes Rock Island and Moline, Ill. and Davenport, Iowa.

Sixty-one of the 75 cities surveyed in the book and job branch l 60 cities in the newspaper branch had increases of at least percent between July 1, 1945, and July 1, 1946.

These net changes were based on the specific rates for 1945 and 1946 weighted by the
ership reported in 1946. Only comparable data for both years were included. Specific in-
es for 1946 reflected a larger percentage change in those cities with relatively low actual
. Thus, if rates of pressmen in city A increased from $1.00 to $1.10, a gain of 10 percent
egistered. If in city B rates rose from $1.40 to $1.50 the change was only about 7 percent.

Charlotte, N. C., in the book and job branch, and Worcester, Mass., in the newspaper branch, reported the smallest increases, 2.8 percent (3.5 cents) and 5.4 percent (7.7 cents) respectively.

Weekly Hours [4]

TREND OF WEEKLY HOURS

Reflecting the reductions in straight-time hours between July 1, 1945, and July 1, 1946, was the drop of 2.5 percent in the index of union hours, which affected almost 40 percent of the book and job workers and 7 percent of the newspaper tradesmen. Among the 18 cities reporting hour reductions in the book and job branch were such important printing-trades areas as New York and Chicago where as many as 70 percent of the tradesmen benefited by shorter workweeks, several trades by as much as 5 hours. In New York all of the trades, except electrotypers and photoengravers, and in Chicago all except cylinder pressmen, press assistants and photoengravers reported shorter hours.

In the newspaper branch, although 20 cities recorded reduced straight-time workweeks, these reductions involved only a few trades and relatively few workers in each city.

TABLE 9.—*Indexes of union weekly hours in all printing trades, 1907 to 1946*

Year	Indexes of weekly hours (1939=100)			Year	Indexes of weekly hours (1939=100)

[1] Combined data for the years 1907-10 not available.

---

[4] Weekly hours considered here refer to the maximum number of hours per week permitt by union agreements before overtime rates become effective. The number of hours actual worked in any week may be greater or less than the weekly hours discussed.

A decline in the index, comparable to that of the past year, occurred in the post World War I year of 1920 (2.9 percent). The most marked index change (a 6.1 percent decline) was registered the succeeding year. This was a reflection of the mounting acceptance of the 44-hour week in the organized printing-trades establishments.

UNION HOURS IN 1946

The straight-time workweek stipulated in union agreemen averaged 38.3 hours for the book and job branch and 37.5 hou for the newspaper branch. Significant hour changes have take place in the book and job branch since the previous surve Whereas more than 9 of every 10 members had workweeks 40 hours on July 1, 1945, the ratio in this category dropped July 1, 1946 to 5 of every 10 members, with most of the mainder shifting toward workweeks ranging from 35 to 3 hours. While 40-hour workweek provisions encompassed most the members of 6 of the 11 book and job trades, all except el trotypers and photoengravers had at least one-quarter of th members with workweeks of 35 to 37.5 hours. The photoengraving union, with over two-thirds of its members under contracts specifying workweeks of 37.5 hours, was the only group having as much as one-fifth of its membership with straight-time weekly hours limited to 35.

TABLE 11.—*Percentage distribution of union members in the printing trades, by straight-time hours, July 1, 1946*

Less than a tenth of 1 percent.

Agreements providing for a 37.5-hour workweek covered a ajority of the newspaper tradesmen. Of the remainder, over e-quarter had workweeks of less than 37.5 hours and one-fifth erated under provisions for 40 straight-time hours per week. Night-shift newspaper crews generally had shorter straight-ne workweeks than the day-shift crews. Thirty percent of the day members, contrasted with 10 percent of the night workers, had workweeks stipulating 40 hours. Two-fifths of those employed on night operations had workweeks calling for less than 37.5 hours whereas fewer than 15 percent of the day men were in this category. Night-shift pressmen and pressmen-in-charge, with over one-third of their membership working 35 hours per week, had the greatest concentrations in the 35-hour category. Night-shift stereotypers, with almost two-fifths of their members under contract for less than 32.5 hours and one-third working 37.5 straight-time hours, registered the lowest weekly hour average (35.3).

Overtime and Sunday Rates

With little exception the union printing-trades members worked under agreements providing for the payment of time and a half for work beyond specified daily or weekly hours. Several agreements, covering but few members, however, stipulated either double time or other than standard rates for overtime.

Eight out of 10 of all printing-trades workers covered (93 percent of those in the book and job branch and 51 percent in the newspaper branch) were employed under contracts requiring double-time pay for unscheduled work performed on Sunday or the seventh consecutive workday. Virtually all of the others received time and a half for Sunday or seventh-day work. Business operations in newspapers frequently require seven consecutive days of operation, but generally any time worked over five shifts by the individual union member requires payment of overtime rates.

TABLE 12.—*Percentage distribution of union members according to overtime an Sunday rates, July 1, 1946*

Trade	Percent of members receiving overtime rates of—				Percent of members receiving Sunday rates of—

Paid Vacations

In July 1946 most of the printing-trades workers in 75 cities operated under union agreements that provided for vacations with pay. The most common provision, affecting over 50 percent of the union members, called for 2 weeks' vacation after 1 year of service. This plan covered a larger proportion of newspaper than book and job people (64 percent compared to 48 percent). A paid vacation of 1 week after 1 year was next in importance in the book and job branch covering over 20 percent of the workers, while a vacation of 1 week after 6 months and 2 weeks after 1 year was the second most common plan in newspaper shops. The plan that generally met the approval of the War Labor Board in manufacturing industries in late war years, 1 week after 1 year and 2 weeks after 5 years, included only about 6 percent of all printing-trades workers. A substantial proportion of union members were covered by other miscellaneous provisions such as 1 veek after 1 year and 2 weeks after 2 or 3 years. A good number f the vacation plans mentioned above provided for breaking the acation period down on a day basis so that substitutes would ot be without paid vacations. Under this system, plans that called or 2 weeks after 1 year required that 1 day's vacation should be redited for each 25 or 26 days worked; those that called for one eek provided for one day of vacation credit for each 50 or 52 ays worked.

The vacation pattern was about the same for each of the indi- dual trades in the newspaper branch. In the book and job ranch, however, bindery women, electrotypers, and pressmen had latively fewer members receiving 2 weeks' vacation after 1 year service than the other trades. Pressmen had more members in e 1 week after 1 year classification and bindery women had a bstantial proportion in the same category, with many additional rkers also getting an extra week after 5 years of service. In e case of the electrotypers, fewer than a quarter worked under e 2 weeks after one year plan; about 30 percent received either veek after 1 year or 1 week after 1 year plus an extra week er 5 years of service. Over two-fifths of the electrotypers op- ted under other vacation arrangements, some of them being re favorable than the 2 weeks after 1 year provisions men- ned above.

Apprenticeship in the Printing Trades

The international union constitutions and the by-laws or working rules of the local unions generally limit the number of apprentices that may enter a printing craft to a specified ratio of the total number of journeymen union members. The ratios generally permit 1 apprentice for each 5 to 10 or more journeymen. In view of recent public discussions indicating that there were insufficient young men in training in the industry, Bureau representatives endeavored to obtain from local union officials details regarding the apprentice situation.

Analysis of the composition of the apprentice labor force indicated an average of 1 apprentice for each 11 journeymen on July 1, 1946. About a third of the 375 printing-trades locals included in the study revealed that union regulations permitted the employment of more apprentices than were indentured at the time of the survey. About 85 percent of the responding locals reported that they were against changing the long established apprentice journeymen ratios to increase the number of apprentices permitted. A majority of the locals reported that the percentage of journeyman rate customarily paid to apprentices had been increased since 1939, indicating that where the starting rate might have been 50 percent of the journeyman rate in 1939, by 1946 it was 60 or 65 percent with increasing percentages after specified periods of training.

BUREAU OF LABOR STATISTICS
EWAN CLAGUE, *Commissioner*

Summary of Proceedings
of
Conference on Productivity

October 28–29, 1946

Bulletin No. 913

For sale by the Superintendent of Documents, U. S. Government Printing Office
Washington 25, D. C. – Price 15 cents

Letter of Transmittal

UNITED STATES DEPARTMENT OF LABOR,
BUREAU OF LABOR STATISTICS,
Washington, D. C., May 1, 1947.

HE SECRETARY OF LABOR:

I have the honor to transmit herewith a report which summarizes the
roceedings of the Conference on Productivity, held in Washington on
)ctober 28 and 29, 1946. This summary of the voluminous proceedings
vas prepared by Mrs. Celia Star Gody, of the Bureau's staff, and was
ubmitted to the participants in the conference, for their editorial ap-
roval. The report also includes an evaluation of the conference by
olomon Fabricant, of the National Bureau of Economic Research, who
cted as chairman of the executive committee which planned the details
nd agenda of the conference.

The conference brought together an outstanding group of research
vorkers from labor, industry, government, and the universities for a
utual exchange of views on a topic of great current importance. The
onference may confidently be expected to have a beneficial effect on the
ontent and direction of research activities in the field of productivity for
any years to come. This report is designed to make generally available
e discussions and results of the conference.

EWAN CLAGUE, *Commissioner.*

ON. L. B. SCHWELLENBACH,
Secretary of Labor.

Bulletin No. 913 of the
United States Bureau of Labor Statistics

Preface

After the close of the war, in 1945, increasing attention was given in ublic discussion to the subject of productivity, and in some instances arp controversies arose. Some differences of opinion seemed rooted divergent interpretations of scanty data; others could apparently be aced to such basic difficulties as lack of agreement on the meaning and gnificance which should be attached to the term productivity. Many ersons felt that under these circumstances a mutual exchange of views the conceptual and measurement problems in the field of productivity ight help materially to substitute agreement for argument.

The Bureau of Labor Statistics of the U. S. Department of Labor d the Division of Statistical Standards of the U. S. Bureau of the dget joined in sponsoring a Conference on Productivity to be attended representatives of labor, industry, private research groups, and gov- nment agencies. The agenda and details of the conference were planned an executive committee which included members representing labor d industry, selected with the advice and assistance of the major labor d business organizations.

The conference was held on October 28 and 29, 1946, at Washington, C. It was attended by about 100 active participants and approximately equal number of observers.

This bulletin is intended to make available to others the ideas which re developed during the two days of the conference. The following es present an evaluation of the conference by Mr. Solomon Fabricant the National Bureau of Economic Research, who acted as chairman the executive committee; the official program of the conference; and igest of the proceedings of the conference. The digest was prepared Mrs. Celia Star Gody of the Bureau of Labor Statistics, a member he executive committee. This digest was submitted to the participants he conference for their editorial approval.

he membership of the executive committee which made arrangements the conference was as follows:

enry B. Arthur, Swift & Co.
olomon Barkin, Textile Workers Union of America, CIO.

George Brown, United Association of Plumbers and Steamfitters, AFL.
Katherine P. Ellickson, Congress of Industrial Organizations.
W. Duane Evans (Secretary), U. S. Bureau of Labor Statistics.
Solomon Fabricant (Chairman), National Bureau of Economic Research.
Celia Star Gody, U. S. Bureau of Labor Statistics.
Everett Hagen, National Planning Association.
Douglas H. Holmes, Westinghouse Electric & Manufacturing Co.
Thomas Mills, U. S. Bureau of the Budget.
Margaret Scattergood, American Federation of Labor.
Ernst Swanson, U. S. Chamber of Commerce.
Samuel Thompson, U. S. Department of Commerce.
Charles Young, Westinghouse Electric & Manufacturing Co.

Summary of the conference, by Samuel H. Thompson..........

CONFERENCE ON PRODUCTIVITY, OCTOBER 28–29, 1946

An Evaluation of the Productivity Conference

The aims of the conference, as set forth by the executive committee r the conference, in inviting participation, were as follows:

> he subject of productivity is generally recognized to be of unparalleled current ortance. It is directly related to the employment and unemployment prob- . It is at the center of any discussions relating to wages, prices, and profits. It cts the ability of the United States to maintain its position in international trade. s the means whereby a constant improvement in the living standards of American ilies is achieved. Despite the importance of productivity, there is lack of agree- nt on the concepts and measures which are appropriate to its evaluation and on implications of current measures.
>
> n this situation, a technical conference is planned as a forum for the discussion productivity concepts and measurements, in the hope that this will clarify and lve genuine differences in viewpoint which now exist in the field. The conference also provide a vehicle for discussing the current state of knowledge regarding luctivity and labor cost, the adequacy of present programs, and related questions.
>
> he conference is sponsored jointly by the Bureau of Labor Statistics of the S. Department of Labor and the Division of Statistical Standards of the U. S. eau of the Budget. The conference is not intended to act as an official advisory , but rather to be a discussion meeting. Papers will be presented by invitation elected subjects, but there will be ample provision for general discussion. Further erences may be scheduled, depending on the wishes of the participants.
>
> limited number of participants will be invited from labor, industry, government, ate research agencies, and academic institutions, and will be present in their idual capacities, not as official representatives of organizations. The participants be selected from among those who may be expected to contribute to the discus- of productivity.

arents are always a little startled to find their infants grown up and a bulk and personality of mature proportions. The sponsoring cies and the executive committee were similarly surprised to dis- r what had come out of this invitation. Instead of a small group of nicians mulling over some rather abstruse concepts and measurements, e assembled over 200 people, all told, from labor, business, govern- t, research, and the academic world, engaging enthusiastically in a d discussion. Interest was fully as great at the end as at the beginning e two solid days of discussion.

t it should not have surprised us too much. The American people come to see the value of a wide and firm basis of accepted fact mutual understanding as a common meeting ground. They know that

it is the only sure foundation for threshing out common problems. They
realize that concepts and measurements are essential in the building of
this foundation, and therefore that concepts and measurements are well
worth discussion. The conference provided a forum for a free discussio
and demonstrated the value of joining persons of diverse points of vie
in it. This was a real accomplishment, perhaps the outstanding accom-
plishment of the conference. It showed how wrong are those who stres
only differences and clashes of interest, who deny the possibility or valu
of meeting on a common ground of accepted fact and standard usage
who see all things simply as matters of opinion.

The conference of course also yielded fruits of immediate bearing o
the question at issue, namely, concepts and measurements of productivit
The abstract of the proceedings which follows summarizes fairly exten
sively the successive statements and remarks of the various participant
and clearly indicates the value of the discussion. The reader will want t
study this record with the care it deserves. It is desirable, however, t
preface the abstract by a review of and commentary on what came out
the conference, along other than chronological lines; and to indicate,
the same time, plans for the future work declared so necessary by all w
attended.

Definitions and Measurements of Productivity

First of all, the discussion clearly brought out how general is the ter
"productivity." The term relates to a whole family of concepts rath
than to any specific member of that family. Almost any comparison
output with input is covered by it. Output may be defined in various wa
however, and input may be measured by one factor or another or
several factors in combination. Further, productivity may be the relati
between output and the input of one factor, all other input factors bei
kept constant, as in an experiment under controlled conditions; or it m
be the relation between output and the input of one factor, with chan
occurring in all other factors. Still further, productivity may be the r
tion between the total output and input of a period, or it may be the r
tion between the increment in output associated with the addition of
unit of a given factor of production; that is, it may be "average"
"marginal." Thus, economists writing on the "theory of marginal p
ductivity" use the term quite differently from statisticians who comp
indexes of productivity. Even statistical measures of productivity
differ among themselves, fundamentally, as well as in detail. To av
confusion, therefore, it was agreed that the term "productivity" be u
only in a general way to describe the area with which the conference
concerned, and to use more specific terms in referring to particular

ts or measurements. "Physical output per man-hour," for example, is ter than "labor productivity" as a term descriptive of most currently plished indexes. Since no reasonably short term can be completely criptive, however, it was felt that terminology should always be defined explicitly as possible whenever used.

temming from the acceptance that there is a whole group of producty concepts was the realization that a variety of measures is possible. asures may be made of output per unit of capital equipment or per of labor; of output per man or per man-hour; of physical output man-hour or value output per man-hour; of "net" physical output man-hour or "gross" physical output per man-hour; and so on. re is no way of deciding which measure is appropriate, except with tion to a particular purpose. For different purposes different measures be suitable. Even for a particular purpose, several different measures be better than one; they may complement, rather than compete with, another. With a variety of measures possible and desirable, it is of se all the more necessary to label each carefully and define each rately. Just what these purposes are and what indexes are most able for particular uses remain subjects for further investigation. e the conference pointed up a job to be done.

onsiderable attention was given to currently prepared measures of ut per man-hour, and also to some historical measures; and various tions were raised concerning their scope and accuracy. It goes withsaying, of course, that no current or even historical statistical index hope to attain complete coverage and perfect accuracy, but there are ees of accuracy and coverage and it is well to strive for the highest oth. The discussion and critical comments brought out at the conice will, I am sure, stimulate even greater efforts on the part of piling agencies to better their indexes. Almost as important, it will them to indicate as fully as possible the margins of error and the ations of representation inevitably still resident in their measures. imber of the criticisms raised at the conference had already been coned by the compiling agencies and had been determined to be of small ficance. However, the discussion taught one clear lesson: results of considerations and evaluations of limitations should be made public, erably in advance of the appearance of criticisms. The range of ts that beset consumers of statistics concerning their validity must irrowed.

iny of the points raised in criticism were, in essence, that alternative ods and measures are possible and perhaps desirable. Some of these isms can be satisfied by a variety of carefully defined measures of ictivity. Others require further examination and discussion before their comparative merits and demerits can be understood, and the discu sion thus provides a list of topics for further investigation, such as th following:

Choice between value weights and man-hour weights, in combining diver physical units of output.
Adjustments for changes in coverage of output or employment by samples products or samples of establishments.
Hours paid versus hours worked.
Machine-hours versus other measures of capital input, such as deflated capi assets.
Quality changes in products and materials, and the development of entirely n products and materials.
Ways of combining different types of input and the related problems choosing between weighted and unweighted aggregates of labor input.
Treatment of overhead, maintenance, and other indirect labor.
Analysis of the representativeness of the sample group of industries for wh current indexes of productivity can be prepared.
Attainment of consistency of measures at the national level with measures subsidiary levels, such as the industry, the plant, or the job level.
Measurement of productivity in long-cycle or custom industries.
Measurement of productivity in service and trade.

We need, especially, to learn the quantitative importance of some these questions.

Limitations of Basic Data

Discussion of the limitations of current indexes indicated their obvi dependence on the availability of basic statistics. No index can be m better than the data which it summarizes. A deeper appreciation t came out of the conference of the great need for more and better ba data collections. Many of the questions raised concerning the accur of the current indexes, for example, can be answered finally only w we can check our current sample statistics against complete surveys s as the Censuses of Manufactures and Mines. Indeed, if such "ben mark" data were made available at reasonably frequent intervals, many these questions would never arise. We need not only more Census s veys, but also to collect more information in them: for example, infor tion on capital assets, equipment, and kinds and quantities of mate consumed. This information should be presented in detail—for exam by size of plant. In addition to complete surveys, there is of co need for broader and more intensive current surveys by government a private organizations, if the information on contemporary change i productivity is to possess the accuracy and scope desired. One of t interesting facts brought out was the rather widespread lack eve private plant records on productivity changes. It is probably fair to re conference as favoring wholeheartedly the most comprehensive statis- possible, as a basis for learning from the past, reporting on the ent, and guidance to the future.

Factors in Productivity

ith the discussion ranging over the full list of different kinds of t—materials, fuel, and use of capital equipment, for example, as well bor—attention was drawn to the possibilities of reducing the require- s, per unit of product, of factors of production other than labor. les labor savings there could be—and the historical records show been—savings of materials and other factors. The more efficient ction of energy from coal is an example.

is may be put differently, to fit the view of many of the discussants. r can be and has been saved directly, by cutting man-hour require- s for a given job or volume of production. Labor can be and has saved also indirectly, by cutting fuel and capital and other require- s for a given job or volume of production. Fuel, for example, em- s in large part labor put into production at earlier stages of produc- To save a ton of coal means to save the labor of coal miners, of ad workers, of distributors. These indirect labor savings contribute ir advancing standard of living as definitely as do direct labor gs themselves. The gain from increased productivity is equal to the of all these direct and indirect savings, and not merely to the savings e factor of production.

th this recognized, conference discussion advanced to another, re- point. When material or capital savings occur, these are to be to direct labor savings to get a measure of productivity increase; hen more materials or more capital are required to turn out a unit oduct, then direct labor savings must be offset correspondingly. To extent increases rather than decreases in unit material or capital ements have occurred is determinable only by appeal to the facts. It uggested by some speakers that, on the whole, material require- per unit of product have been reduced rather than increased; and e period of increasing capital investment relatively to output, so teristic of early industrial development, had more recently been ed by a period in which many industries' capital requirements per ere reduced. It is important to distinguish carefully between long- rends and shorter movements, however, and between one industry nt and another. Broad generalizations always imply exceptions. too, there is open a field for serious research and historical study. recognition that in an industry or plant various factors cooperate job of production, that these influence one another, and that they

are also influenced by factors outside the industry or plant, advance
understanding in still another way. The discussion at the conference high
lighted the dangers of imputing responsibility for advance—or decline-
in productivity to any one factor. To isolate the influence of a singl
element in a complex process has always been the most difficult proble
of science. It has been solved, satisfactorily, only in the physical science
where experimentation under controlled conditions has been develope
In the social sciences, statistical methods to accomplish the same aims ar
still in the process of development, and in any case, the data to which t
apply these methods and the skill with which to interpret the results ar
largely lacking. This does not mean that now and then the immedia
cause of a particular change cannot be determined; but this is probab
rare, and determination of the ultimate cause is quite another thing. A
one speaker so well put it, shall we try to figure Lord Kelvin's contrib
tion in assessing the factors aiding in recent developments in electr
motors? To try to determine credit or responsibility is to enter an endle
maze. Only in Heaven will judgments of this kind be made and grac
fully accepted.

As planned, emphasis was placed in the conference on questions
concept and measurement. Effort was made to avoid such controvers
and speculative matters as how to divide the gains from productivity. I
evitably, however, the talk at the conference touched—even if lightly
on such matters as wage rates, profits, and prices, as well as numbers
workers, volume of equipment, and volume of goods produced, for
viously there are important questions of developing and maintaining
centives to raise productivity. There are questions of the bearing on p
ductivity of "balance" among industries, plants, and factors of prod
tion, of "equilibrium" of costs and prices, incomes and expenditur
The important fact could not be overlooked, that raising the Nation's p
ductivity is an economic problem, not merely a problem of technology
engineering. More must be learned not only about concepts and measu
ments but also about the economics of productivity, if the factors det
mining our economic progress are to be ascertained. The confere
members showed great awareness of our ignorance of the economics
productivity. It is for this reason that they stressed the need for m
work in analyzing this intricate set of relationships. Only by coming
grips with this problem can a decision be made as to the concepts
measurements needed.

Work Still to be Done

It is hoped that this quick review will give the reader a notion of
went on and stimulate him to read the more detailed story that foll

though, naturally enough, the main points of agreement have been essed, in a sense the conference may be summarized also by saying that accomplished not so much explicit agreement on particular points as ter understanding and appreciation of diverse points of view. This , however, implies agreement that more work has to be done.

This means more work of the type that has been done. Understanding the facts concerning productivity and the factors stimulating (or reding) advances in it is furthered by the preparation of current indexes orting changes in such quantities as output per man-hour and labor t per unit of product. These indexes can be increased in number and proved in construction. They are valuable. Understanding can also be adened and deepened by other types of work. Studies of marginal costs l of the functional relation between production, labor and capital (the oduction function"), are interesting approaches which should be conied. Studies of such relationships as the following also need to be conied and expanded:

Changes in productivity in relation to changes in selling prices, employment, wages, and other economic quantities.
Variation in productivity among plants of different size, age, and organization.
The extent of and reasons for international differences in productivity.
The origin and diffusion of technological developments of all sorts.
The economic histories of particular industries and of the relations between industries.
Obstacles to the introduction of technological advances.
Cyclical changes in productivity.
Productivity differences among individuals.

n attacking a set of problems with such wide ramifications, no apich or aspect should be neglected.

became apparent during the conference that the participants not only ize that much work remains to be done in this field but expect the connce, acting through the executive committee, to carry on a good deal his work and stimulate its undertaking in other quarters. It is approte therefore to report the plans now being made by this committee to y out the mandate laid upon it. It is hoped to start a series of round- discussions at which experts will be asked to present papers or rwise lead discussions bearing on particular and well-defined ques- related to productivity. These questions will be drawn from those n above and from additions to them. Participating in the discussions be not only members of the committee but also other persons qualified ntribute. It is hoped to keep the groups small and active—essentials intensive discussions of technical subjects. The discussions will be available to the public in the form of papers or abstracts published ppropriate journals or bulletins. It is expected, also, that as experience with the discussions accumulates, it will again be desirable to arrange a large-scale conference, open to a wider audience, to discuss the past work, bring to public attention the work currently being done in this area, and plan for the future.

Obviously, no one group can hope to do all the work required. Consideration should and must be given to these various questions by men and women throughout industry, labor, academic circles, and government. Experience with particular industries and access to special bodies of data are real advantages possessed by many of these persons. It is hoped that they will bring these advantages to bear effectively on the common problem. It is hoped, too, that they will advise the sponsoring agencies, through the chairman or the secretary of the executive committee, of the work they are doing. With all thus working intensively, in constant touch with one another, there is hope of enlarging the broad conceptual and factual basis so valuable as a common meeting ground for persons and groups with diverse points of view.

Solomon Fabricant,
Chairman, Executive Committee,
Conference on Productivity.

Summary of Proceedings

OCTOBER 28—MORNING SESSION

Chairman, Leon Henderson, Research Institute of America

Welcome to Conferees

STUART A. RICE (Assistant Director of the U. S. Bureau of the Budget) : A warm welcome is extended to the members of the conference. The conference was arranged through an executive committee composed f representatives of management, organized labor, the Department of Labor, the Department of Commerce, and the Bureau of the Budget. The ork of the National Income Conference in clarifying and developing oncepts in that field should be noted. It is hoped that the Productivity Conference will contribute to greater agreement on productivity concepts nd to the improvement of measures of productivity.

Scope of Conference

EWAN CLAGUE (Commissioner of Labor Statistics) : The conference as not called to discuss means of improving productivity or the methods hereby the social benefits of production economies should be divided or istributed. Its purpose is to reach agreements, if possible, on what ysical facts of the economy the word "productivity" should cover. The nference may wish to differentiate the various concepts now encomssed by the term "productivity," both in definitions and measurements. he participants will discuss the indexes and measures of productivity w available, what they cover in the way of physical facts, and what ysical facts they ignore or obscure. The meeting will also consider eans of improving measures of productivity, extending them, and makg them more useful to greater numbers of persons. It is hoped that the nference will give direction to all research in this field, both private and blic.

The conference is to be a discussion meeting in which the members rticipate. A transcript of the proceedings will be taken but will not made available for general distribution. A summary of the proceedings ll be distributed to all participants. After approval of the participants, s summary may be made available to the public. A limited number of blications representatives have been admitted to the conference, with understanding that no quotations will be attributed to individuals cept with their express permission. Moreover, all individuals represent mselves only and not their organizations.

Productivity and Its General Economic Setting

Robert Nathan (Robert Nathan Associates): Although the conference is concerned only with the questions of concepts and measurements, clarification of these questions would help in policy considerations.

Over the past half century, there has been a tremendous increase in productivity in terms of the relationship between output and every factor of production. The increase in productivity has not been limited to a rise in production in relation to man-hours worked. It is probable that productivity has also increased as regards the relationship between production and capital equipment, provided capital equipment is measured not in dollars but in terms of the efforts and resources put into capital equipment.

This increase in productivity has many implications, one of the foremost being its relationship to the question of employment. In the past, when the problem of technological unemployment was discussed, it was thought that there was only a given volume of production to be created and that when increased output per unit of effort was achieved, the total effort previously used would not be required. However, as a consequence of analysis of what people can consume, the concept of technological unemployment has begun to be replaced with positive and constructive thinking of full employment. The benefits of increased productivity should be considered in terms of standards of living rather than of technological unemployment. The more rapid technological development and the more speedy increase in productivity that may take place in the future is not a threat and must not be regarded as a threat to full employment. Society must make certain that, as output increases, employment is maintained, so that participation in consumption and production shall not be narrowed to a limited and decreasing percentage of people.

On the basis of the speaker's experiences overseas, it appears that the rest of the world is just beginning to recognize the importance of productivity in the development of the tremendous economic power of the United States. In France, for example, there is a keen recognition of the need for industrial development, modernization, and higher productivity if the nation is to be able to compete in world activities with the United States, Great Britain, and other countries. Moreover, other countries look to the United States for leadership, for guidance, for "know-how," for help.

Productivity also has significant implications with respect to domestic policy on wages, prices, and profits. Increased consumption can emerge only through production. Monetary benefits to any group mean nothing unless expressed in terms of real output and real consumption.

Problems of Concepts and Measurement in the Field of Productivity

HIRAM DAVIS (Director of Industrial Research, Wharton School, University of Pennsylvania): Most persons, in using the term "productivity" have meant the physical output obtained for a given physical input. The usual measure of productivity—output per input of labor—is inadequate, however, since one input factor is used to represent all input. The change in output per man-hour may be greater than the change in output per unit of total input, for example, when power or machines have been substituted for labor. On the other hand, even though man-hour output shows no change, the input of other factors may be changing materially. Thus, capital consumption may be speeded up by obsolescence or reduced by improved machines with a longer service life. Input factors cannot be measured by money costs, since money costs are both a measure of input and a measure of what the input agents receive.

Several methods of measuring input have been suggested. The embodied labor method involves the expression of machinery and other factors in terms of the labor content represented. One difficulty is that it is not possible to express risk-bearing, for example, in terms of labor content. Moreover, it is extremely difficult to express capital consumption in terms of labor content. Another proposal is the use of costs at constant prices. However, there is the practical objection that the compilation of appropriate indexes for correcting the value series is extremely difficult. Because of the many difficulties in the measurement of total input, it might be more useful, for analytical purposes, to develop a series of ratios relating output to each of the important input items.

Change in the composition of output, the substitution of new products for old, and changes in quality all make it extremely difficult to measure output. The equivalent-unit method—the method of reducing output of different grades to an equivalent grade—involves the problem of the method of conversion used. If prices are used as weights, the output measure may be influenced by differences in marketing methods or differences in demand for the various classes of products. If labor time is used as weight, the output series would correspond to the man-hour series. Another method proposed is the potential service of the commodity, for example, tire-miles. Although this measure is useful for certain purposes, it has its limitations. In the case of tires, it would credit the tire industry for improvements in automobiles, in highways, and in the quality of crude rubber, that were brought about by other industries. Many indexes of physical production are weighted by value or value added. Since value added changes from year to year, depending upon profits, it may be desirable, where possible, to refine the value-added weights to the point where they represent manufacturing costs.

Since the problem of measuring output falls particularly at the industry level, it is hoped that out of the conference may come a decision to develop working committees in each of the important industries.

In connection with input measurement, it might be desirable to consider not only the input used up, but also the input supply assembled for an undertaking. Another important concept is the measurement of output not only in relation to physical factors, but in relation to real costs.

In relating output to man-hours, it might be preferable to express the results in terms of labor requirements per unit of output rather than output per man-hour. A similar form might be used in showing the ratios between output and capital and other production factors. The term "productivity" might well be restricted to those cases in which it is possible to present more than one measure of input or in which the broad sweep of developments over a substantial period is considered.

Concepts and Measures of Productivity at the Job Level

Martin Gainsbrugh (National Industrial Conference Board):[1] A questionnaire was sent out to the NICB panel of business executives, concerning changes between the prewar and current period in labor productivity on comparable jobs performed under comparable conditions. The reports indicated a general dissatisfaction in industry with the term "labor productivity." Some replies indicated a belief that the number of labor hours per unit was determined primarily by the type of equipment and not by human factors. Many companies had no measures either of productivity on comparable jobs or of output per man. Several measures were used in the replies—output per man, dollar value of products per productive man-hour, dollar sales per employee, etc. Although the survey indicated that there is an interest in labor productivity, few plants have quantitative information on this subject.

Nathan Spero (United Electrical, Radio and Machine Workers, CIO): Management has been carrying on a Nation-wide publicity drive, singling out worker effort as the important factor in productivity and implying that worker effort has decreased. This campaign obscures the fact that the effort of the individual worker is inseparable from many of the other important factors that affect productivity. Worker effort is affected by such factors as patriotism, the cost of living, profits, and other influences. A constant flow of materials of the right quality is extremely important to efficient production at the worker's level. Shortages of materials have resulted from speculative stock piling to anticipate price increases or hoarding to force price increases. In addition, the nature of the plant's physical equipment determines, to a large extent, the worker's efficiency. The efficiency of the workers also depends on the efficiency of management. Frequently management has raised the cry of decreased workers' effort to hide its own shortcomings. Similarly, systems of wage payment influence worker effort. Incentive systems provide some estimate of the extent of productivity increase and of the extent to which management passes along the gains resulting from increased productivity. However, even incentive systems can sometimes be turned into their opposites, resulting in a lack of incentive for production. Finally, relations between the company and union have an extremely important effect on worker efficiency—for example, the way in which negotiations are conducted, the way the grievance procedure operates, and the nature of supervisory relationships.

---

[1] Editor's Note—The remarks of Mr. Gainsbrugh, scheduled for the morning session, were actually delivered in the afternoon. They are given here for the sake of clarity and in order to round out the presentation of the subject. The same was done in a few other cases.

Discussion

Solomon Barkin (Textile Workers Union of America, CIO): Management has employed numerous measures which allegedly measure output. The one which is very widely used is the time study. It is not a true measure of productivity. It provides a method of judging, through inadequate means, the increase in output expected for varying additions in the application of human effort and skill. Many incentive systems are based on the premise that labor should be compensated only for the additional output which arises from more than normal effort and skill. They therefore recapture all increases in output arising from causes other than human effort and skill. They do not measure output. Measures of physical output which do not seek to distinguish the source of the increased output more nearly conform to the measure which is being sought. Thus, for example, incentive systems which provide payment for output and which do not allow for the change of this rate for any cause more nearly approximate compensation for increased productivity from all sources. During the war certain plant-wide incentive systems were based on his principle.

H. B. Maynard (Methods Engineering Council): Difficulties are in-olved in establishing performance ratings. With fixed methods, the ontribution of the worker to production is dependent on his skill and n the effort with which he works. While performance ratings are based n a process of judgment, it is possible to achieve a fair degree of onsistency by using carefully worked-out definitions, motion pictures epresenting different performance levels, etc. Another approach to this problem is effort rating, which endeavors to arrive at an evaluation of performance level by judging the speed of the motions made by the operator. A different approach being evolved establishes, as the result of considerable research, predetermined motion time standards which, if once accepted, will take the element of judgment out of the problem.

LAZARE TEPER (International Ladies' Garment Workers' Union, AFL): Mr. Maynard has discussed the question of measuring efficiency at the job level under fixed conditions, but the main problem arises when conditions change. If a particular operation is changed, for example, from a 5-motion job to a 4-motion job, efficiency is not always measured in relation to the former 5-motion standard but in relation to a new 4-motion standard, and the worker loses the benefits of increased physical productivity. If labor is not to pass judgment on management's efficiency, performance on the job must be judged in terms of the physical units produced.

H. B. MAYNARD: When a worker, through his own ingenuity, reduces the number of motions involved in a job, he should have a substantial award. However, the standard should be reset and rewards for ingenuity should not be included in the incentive plan. If they are, the earnings structure is distorted, with some workers earning considerably more than others for the same expenditure of effort; the workers themselves consider such a wage structure unfair.

RUFUS TUCKER (General Motors Corporation): Although it is perfectly true that bad morale and bad labor relations result in decreased productivity, output is reduced only because such conditions cause the laborer either deliberately or unconsciously to hold back. Consequently, such conditions should not be charged to management, since the effect in reducing output depends wholly on the laborers' attitude.

MR. CLAGUE: The problem of measurement of productivity at the job level leads quickly to the problem of shares in the output. For example, assume that man-hours per unit were reduced because of the workers' ingenuity, wages were raised proportionately, and the same number of people were at work. Production would be increased, but it would not be possible to sell the whole output at the same prices. One is thus forced to a consideration of wages, interest, rent, and payments for other factors of production. Nevertheless, it is desirable to work out methods of measurement that will not be confused by the issue of sharing the profits. Another difficulty is that the job is constantly changing, and any measure of productivity at the job level cannot be put into a long series. In view of these difficulties, it appears that measurements of productivity at the job level are the concern of labor and management at the particular plant, and both labor and management will have to get into the study of job output.

Gardner Means (Committee for Economic Development): In a boom period there is a small proportion of overhead workers relative to production workers. In a depression, the number of overhead workers may be the same, but the number of operating workers is reduced, with the result that total man-hours per unit of output are increased, even though each worker is just as productive in his particular job. There is a question as to whether such a change should be called a decline in productivity or whether the effect of changes in the proportion of overhead workers should not be separated from other changes.

Hiram Davis: It would be possible to develop a series of ratios, relating output to the various categories of labor and not merely to labor input as a whole. Changes in the proportion of overhead workers may not be only a cyclical relationship; it has been suggested that there is a decided trend in this country toward an increase in the proportion of overhead workers.

(Seth Levine of the CIO Maritime Committee, Charles E. Young of Westinghouse Electric & Manufacturing Co., and Rosalind Schulman of the Industrial Union of Marine and Shipbuilding Workers of America also discussed briefly the relationship between productivity and the level of output.)

Duane Evans (U. S. Bureau of Labor Statistics): Cyclical changes are not so likely to affect measures of productivity at the job level as at the industry level. Physical output per unit of labor input is of primary importance, rather than per capital input or input of other factors. On the one hand, the physical output produced determines the standard of living. On the other hand, the labor force is the one resource whose utilization cannot be deferred. Tremendous numbers of separate things determine the output of the individual worker—management factors, mechanical factors, machine factors, materials factors, and worker factors. A very big element in the high productivity of the United States is the accumulated skill and experience of the labor force, which is not wholly industrial but is due, in part, to familiarity with mechanical devices in daily life.

There is no typical situation with respect to reports concerning worker effort. Some plant-managers have stated that their labor force is better today than when we entered the war, while others hold strong opinions to the contrary.

Robert W. Burgess (Western Electric Co.): Referring to remarks by Mr. Barkin and others which questioned the accuracy of available measures of output at the job and plant level, as a matter of concept, measures of productivity (according to the orthodox definition of output divided by man-hours worked) could readily be constructed in plants which use the piece-work system with predetermined "standard" costs and standard times for each job. The point is that the concept of productivity in such cases is clear-cut and its measurement available without question. How accurately and fairly standard costs and standard times have been established in any plant is another question, separable from that of the concept of productivity. There is still another question of the operating type: whether day-by-day adjustments should be made in the application of piece-work rates to recognize unusual current irregularities in production conditions.

Solomon Barkin: A piece-rate system does provide for payment in proportion to output. In contrast, engineered incentive systems are based on the concept that there should not be compensation for increased output if the increase is attributable to some factor other than the worker's effort. Thus confusion arises because of the attempt to identify worker's effort and output.

OCTOBER 28—AFTERNOON SESSION

Chairman, Robert Nathan, Robert Nathan Associates

Concepts and Measures of Productivity at the Plant and Company Levels

Benjamin Haskell (United Textile Workers, AFL): The statistical approach to productivity—the measurement of the relationship between output and labor—has very serious and dangerous inadequacies. The desire of the statistician for some single over-all measure is a stumbling block to obtaining genuine knowledge. For example, a variety of very different products may be called by the same name. The averages presented by the statistician often obscure rather than disclose what should be measured.

The statistical approach ignores the meanings and explanations. However, the explanations and qualitative factors are just as significant as the figures. For instance, when a strike broke out at a cotton mill, it was discovered that the employer had bought a poor batch of cotton. On the basis of production during that period, one might conclude that labor was falling down on the job, but the factor of poor cotton had as much importance as the time input. In the same way, the organization of the plant, labor relations, the kind of machinery, and the flow of materials ıffect the volume of output. Those who handle statistics have a moral ›bligation to give explanations, because the tendency has been to imply esponsibility whenever the statistics show an apparent decline in physical ›utput per unit of labor input.

The farther productivity statistics depart from the plant level, the nore obscure and meaningless they become. The statistical approach hould therefore be supplemented by the case-history approach at the lant level. The case-history approach will provide the qualitative factor, ıe explanation of why things are as the statistics claim them to be. The ıformation will be based on actual experience of management and labor nd not on reported statistics which have many flaws. A valuable byroduct of this approach will be to increase the cooperation of local labor ıd management in matters of common concern, such as productivity.

H. B. MAYNARD (Methods Engineering Council): In considering proıctivity at the company level, it is necessary to include not only the oductivity attributable to the application of the worker but also that tributable to methods. First, productivity is affected by methods deterined by job conditions, including design. For example, in the dress dustry, productivity will depend on the presence or absence of sleeves, llars, pockets, frills, and the like; in coal mining, on the presence or sence of gas, the height of the seam, the hardness of the floor, and nilar factors. Second, methods determined by physical equipment affect oductivity—whether the operations are performed by hand or machine, d the types of machines used. The third method variable, under given › conditions and physical equipment, is the sequence of motions emyed by the operator.

Because of these factors, the measurement of productivity is difficult. ıe various yardsticks used (volume per man-hour, volume per man-day, lume per crew-day, volume per machine-hour, dollar value of sales man-year) measure productivity incompletely and must be used h understanding. General units like tons, molds, and pieces do not relate well with the time and effort required to produce them, if the ge of sizes, weights, etc., is varied. In many instances difficulties have n experienced with incentive plans because differences in the design the products handled resulted in large variations in earnings.

The solution is generally to establish additional units of measure, with tandard for each. In coal mining, for example, instead of a single nage per man-day figure, it would be necessary to establish standards gaseous and nongaseous mines, for various ranges of seam height, various grades of coal, and for various types of physical equipment. ıagement officials, through long experience, are able to establish irical relationships so that even incomplete measures take on value and meaning. However, in order to obtain productivity figures that are comparable and useful at the plant level, it would appear necessary to establish well-defined classifications of product, job conditions, and physical equipment. Then any differences may be attributed to labor effectiveness, including in the latter term such factors as skill, effort, heat, light, ventilation, training procedures, morale, managerial skill, and so on. Such information would appear to be most useful in raising productivity throughout a given industry.

Charles E. Young (Westinghouse Electric Co.): Output per man-hour of factory labor is only one of several interrelated productivity concepts that are important in managing a manufacturing enterprise. For purposes of reaching valid business judgments, comparisons of results with costs must ultimately be expressed in monetary terms. Analysis of physical output per man-hour is useful primarily as a refinement of technique aimed at eliminating the vagaries of money as a means of measurement. However, the concepts and measurements must eventually be reinterpreted into monetary terms.

Physical measurement of productivity at plant and company levels i necessarily inexact. Even if a plant or company produces a single produc all the units of which are identical, problems may arise. If the plant ha been generating its own electricity but later buys its power, for exampl the man-hours per unit of finished product will be reduced, but it i questionable whether this change should be called an increase in produc tivity. Measurement becomes more complex when a second product introduced, for this involves a weighting problem. This lack of hom geneity also applies to man-hours, since there are differences in skill an effort between different individuals and in different occupations. Anoth problem concerns what part of the total hours worked in a plant company shall be used. Because of these difficulties, comparisons pu porting to show differences in productivity must be subjected to the mo careful scrutiny. Possibly the proper function of physical measureme of productivity at the plant or company level is to delineate broad tren rather than to support detailed conclusions as to management acti or wage policy.

Many of the improvements in manufacturing efficiency come ab product by product, or even part by part. There is no reason to supp that each and every operation included in an average has become m efficient in the same degree. An example of productivity change operati virtually on a plant-wide level is the redesign of the electric-motor l of the Westinghouse Electric Co., which resulted in a 30-perc reduction in the man-hours required to produce a given motor. This p gram involved investigation of the characteristics that customers de ı motors, extensive development work, and the investment of 20 million ollars in a new plant. The number of parts required for the new motors 'as reduced by over 90 percent. This example indicates that substantial nprovements in productivity do not accrue merely by the passage of time, ut must be conceived, studied, implemented, and backed by substantial ıvestment.

Many of the forces which operate to increase productivity have little onnection with the earnestness and skill of the individual worker. Among e foremost requisites of growing efficiently is alert aggressive management. Friction between management and workers, however, can hinder ıd even undo many promising technological gains. If friction is replaced mutual confidence and respect, management and labor can go forward gether, to their mutual advantage and to the benefit of the general public.

oncepts and Measures of Productivity at the Industry Level

Solomon Barkin (Textile Workers' Union of America, CIO): This a summary of two papers already distributed to the participants.

One, "Measuring Man-Hour Output in the Synthetic-Yarn Industry," scusses the deficiencies of the index prepared by the Bureau of Labor atistics as well as of an alternative measure prepared by the Textile onomics Bureau. The Textile Economics Bureau production index, ıich is based on the total yardage of rayon yarn, is invalid, for there no direct relationship in the synthetic-yarn industry between yardage d man-hours. The Textile Economics Bureau and Bureau of Labor atistics indexes have a number of deficiencies in common. The comnies in the industry produce many products in addition to rayon yarn d the proportion of these products has continuously increased; for ımple, two plants are devoted exclusively to the production of nylon. is incorrect to derive output per man-hour by dividing an index of on-yarn production by a man-hours index which includes nylon and er products, as well as rayon yarn. Moreover, the man-hours figures primarily the number of man-hours paid for and not man-hours rked. As unions obtain provisions for more liberal vacations and kness and lunch-period pay, the discrepancy between the index of n-hours paid for and the actual hours worked is constantly widened.

Mr. Young: The experience of Westinghouse Electric Co. is that "net owed hours" are about the same as in 1941. Elapsed hours for the entive workers are somewhat lower, and indicate a gain in efficiency. wever, for hourly paid workers, there has been a considerable reduc- ı in the number of "net allowed hours" as against the elapsed hours. addition, there has been a large increase in the number of salaried and staff people, brought in on the expectation of a high volume of output. The company is currently making inefficient use of some labor; this is no reflection on the willingness or skill of the workers, but may be bad management.

Per capita income has been growing at an accelerated rate and it is important that the remuneration of labor be reviewed quite frequently. This should be done by considering total productivity and sharing the increases, making only such distinctions between workers as are possible through very detailed studies of performance at the job level. The general movement of wages must be based on the general movement in productivity. It is possible, by studying the changes in real per capita income of the country as a whole, to determine what changes should be made in the income of labor as a whole to provide equilibrium in the economy. About a year ago the speaker made an attempt of this kind. Assuming that wages, prices, and productivity were in balance as of January 1941, making allowances for the increased cost of living, and projecting the annual productivity increase of the years before the war, it was found that as of August of last year [1945] there was a needed adjustment of 18 or 19 percent in the general wage level. Although thi study yielded only a first rough approximation, it was a starting point

John D. Gill (Atlantic Refining Co.): Repeated attempts to mak measurements of labor productivity in the petroleum industry have bee unsuccessful because of changes in equipment, in processes, in th quality of output, and in the quality of raw materials. The chief reaso for attempting to measure labor productivity is with respect to the remuneration of labor. However, it makes no difference whether labo productivity can be measured at the plant and industry level. It is possibl to depend on competition from department to department, from plant t plant, and from industry to industry, for high labor productivity, in th sense of the workers' attitude and qualities of mind and muscle. It i absurd to think that there can be vast differences in the remuneration o for example, Number 1 machinists in different plants because of differences in productivity at the plants. The apparent differences in productivity between the plants may be almost entirely the result of managemen efforts, which are quite irrelevant to the value of the machinists.

The original interest in man-hour output centered in the question displacement and reemployment, but current interest centers in th creation of new wealth for distribution. Therefore, it is necessary t consider how the results of our industrial activity may be more rationall distributed. Output per man-hour gives one phase of the approach t productivity, but it is also necessary to consider other phases of produ tivity in the sense of creation of wealth at a lower cost. Enormous savin cur in industry through more economic use of materials and savings of erhead items.

The second paper, "Measuring Productivity Rather Than Man-Hour itput In an Industry," discusses changes in total productivity in the tton-textile industry between 1937 and 1939. The value of products, s wages and profits, corrected for price changes, is used to show the out of factors other than labor. Output per unit of input of these factors ist be considered along with output per man-hour. This paper is preited only as an approach to the problem of measuring total productivity l may need refinement.

Discussion

NATHAN FINE (Research Director, Metal Trades Department, Ameri- Federation of Labor): Mr. Young's implication was that shares uld be based on the contribution of the various productive factors. The nmon assumption is a very static one. It is assumed that the worker ys pretty much on the same level, but that the research division has no itation. The status of the industrial arts, which is so largely determined the universities and Government agencies, is taken for granted. In last 4 or 5 years, the Government has invested hundreds of millions lollars in machinery and has given it mostly as free goods to industry. it contribution will automatically be assumed to be the contribution research of the companies. No effort is made to determine what part he workers' products goes into the company treasury for depreciation research, which in turn becomes a company contribution to further elopment. When analysis is made from the viewpoint of relative tributions and it is assumed that management takes over everything ept the workers' contribution, the whole question of productivity lies something which is a little pernicious from the labor standpoint. tudies were made plant by plant, or job by job, and all the factors e analyzed, the common assumptions would not necessarily be shown .

IR. YOUNG: It is agreed that the integration of research activities make fficult to determine the specific contribution of any one group.

ARRY MAGDOFF (U. S. Department of Commerce): There is need relating what is being measured to the purpose of measurement. erent measures are needed for different purposes. There is the onal aspect of distribution of income, from the standpoint of adequate nce to maintain full production and full employment. Secondly, a sure is needed for negotiations with respect to wages. Third, measures needed for management problems with respect to controls and efficiency. In the opinion of the speaker, there is no scientific method of measuring performance on the job. The only constructive way is for labor and management to get together and to settle on techniques and standards.

Mr. Gill: Industrial engineers can do much to affect productivity, in the sense of power to produce, but the individual who might be operating at 80 or 85 percent of his personal effectiveness cannot have that effectiveness greatly increased. The main concern is productivity, in the larger sense of capacity to produce. The problem is to increase total production; this can be done only by attaining and maintaining equilibrium in the economy.

Mr. Barkin: Industrial profit figures are not real indicators of productivity. There is, first, no set rule as to how much industry should receive; nor is there uniformity as to the methods of calculation. The figures usually discount increases in productivity which have been passed on through lower prices and reflect the bargaining powers of the various economic groups. It is therefore necessary to study the relations of various factors that enter into productivity at the industry level.

Everett Hagen (National Planning Association): There is a method by which it is possible to get double entry bookkeeping into our thinking The changes in productivity—total physical output divided by man-hour —together with the change in prices and the shift in the nature of th output should add up to the change in the value of output per man-hour A study made by Sam Cohn, under the direction of the speaker, o the change in the value of output per man-hour between 1939 and 194 both for all nonagricultural industries and for manufacturing showe that for all nonagricultural industries the increase was 55 percent. Th increase in prices may be estimated at 28 percent. Thus, the increase i physical output per man-hour, plus shifts in the nature of the product must have accounted for a 20-percent rise in the value of nonagricultur output per man-hour. It is possible to estimate the change in physic productivity, the effect of the shift in the composition of output, an the change in prices. If all three will not add up to the change in th value per man-hour, then something is wrong with one of the fo measures.

Duane Evans (U. S. Bureau of Labor Statistics): One way of a proaching economies in the use of input factors other than labor is l the use of the interindustry relationship technique. The Bureau of Lab Statistics, for the year 1939, divided the entire economy into maj industry groups and investigated quantitatively the kinds and amou of products which proceed from each industry to the others for furth processing or for use. For example, over the past 20 years there has been a marked reduction in the amount of coal required to produce a kilowatt-hour of electric power. This change does not show up in the productivity figures either for the coal industry or for electric power, but it does show up on the interindustry balance sheet.

Many different types of measures can be useful. In the tire industry, for instance, one can measure the number of tires produced or the total tire-mileage. These may be related to total man-hours, skilled and unskilled, together and without differentiation, or it is possible to separate the man-hours worked by skilled workers and unskilled workers and to weight them to derive an adjusted figure. None of these measures is intrinsically wrong, and each may convey useful information, but the user must understand what is included, what is excluded, and what s ignored.

OCTOBER 28—EVENING SESSION

Chairman, George W. Taylor, University of Pennsylvania

oncepts and Measures of Productivity at the National Level

Marion Hedges (International Brotherhood of Electrical Workers, FL): Whether the United States operates under a free economy, a lanned economy, or a mixed economy, its achievements depend upon roduction. Productivity is a secondary concept, of importance because bears directly on the question of equitable distribution of the results f production.

The salient fact about American industry is that it is mechanized. Our eakness has been that we have never clearly visualized our destiny with elation to mechanized production. Mechanized production enables inustry to pass from piecemeal production with high unit costs to mass roduction with low unit costs. Mass production with low unit cost, howver, must depend upon high income for each citizen. The United States as elected to follow the free-enterprise concept in the operation of our onomy. Our economy can be operated under this concept, but not ithout controls.

An article by Benjamin Graham, in the Commercial and Financial hronicle, presents a point of view in business that may be of great oment. Mr. Graham traces mass unemployment in time of prosperity to persistent tendency for productivity to expand faster than per capita come and to a recent tendency for the working force to expand relative population. Mr. Graham states that wages should advance with proctivity, while the workweek should decline to the extent needed to aintain full employment.

Some way must be found to take into consideration, in any productivity index, intangible values. Moreover, in some industries, as in building construction, productivity cannot be measured quantitatively.

Labor can hope to profit by a more scientific operation of industry, with national goals in mind. Labor believes generally that labor is not now receiving and never has received a just share of the fruits of production. Labor wishes to see the gap closed between the growth of productivity and the income distributed. Labor does not believe productivity can be quantitatively measured, since intangibles are all-important. Labor believes that any gauge of productivity will be advantageous—even physical output per man-hour, but labor wants such a gauge, when promulgated, to be seen for exactly what it is, and advocates that a complete description be published with each set of periodic figures.

EVERETT HAGEN (National Planning Association): The first conceptual problem in the measurement of productivity at the national level relates to the weights to be used to combine into one index the trends for the different types of goods, when the proportions of the different goods change. As an example, assume that the two types of goods are automobiles and tables, with tables representing forest products in general, and that the wage payment per man-hour and the value of output per man-hour are higher in automobile production. The increase in productivity in the automobile industry has been much more rapid than in the forest-products industry. If the two industries are weighted together in accordance with the number of man-hours in each, there will be one result for the combined productivity index. If the weights are the wages in each industry, on the basis that a man-hour at $1.50 is not the same as a man-hour at $1.00, a different index will be obtained. If the price that the final purchasers of the products put upon them and weight by value of product are considered more relevant, still a different combined index is obtained. In general, weighting by value of product is most appropriate.

Another problem is, which year is to be selected in weighting the two series together. If automobiles and forest products are weighted in accordance with their relative importance in 1940, automobiles will be weighted much more heavily than if relative importance in 1900 determined the weights, and the index will therefore go up faster.

The problem of shifts in the proportions of different goods arises between the goods-producing and service-producing industries. In the services, the growth in productivity has been much more slow than in the goods industries. In the thirties, the service industries grew greatly in relative importance, because of disguised unemployment of persons who shifted into small businesses and attempted to sell services. A marked reverse shift occurred during the war. If the trend in productivity for the economy as a whole is estimated by comparing the deflated value of output with man-hours, the effect of shifts between industries is included in the estimate. In the opinion of the speaker it is correct to include the effect of such shifts. Because of such shifts, it was estimated in the Hagen-Kirkpatrick study that the increase in over-all productivity between 1939 and 1950 would be 2.3 percent per year, compared with 1.7 percent between 1923 and 1939.

Another conceptual problem which enters at the national level is the lifficulty of measuring output in some industries. There is no definable unit of output in such fields as the law, services of government workers, anking, and the like. A final problem is the lack of data for some fields, ven where there are no conceptual difficulties.

The conference might consider why there are no data in certain areas, hether there are conceptual problems and, if so, what problems. In this ay, it could make some technical advance in the problem of measuring oductivity.

Robert W. Burgess (Western Electric Co.): Studies of productivity the top level may lead to the formulation of decisions on particular erating questions; studies at the plant level may facilitate the task of nagement; studies at the industry level may furnish a standard of mparison of industries. At the national level two types of measures of oductivity would be desirable. To measure the typical gain in producity that the economy as a whole is making, a composite should be structed by the use of constant weights applied to the productivity ies for the different industries. On the other hand, to meet the probs raised by Mr. Gill and others concerning changes in total product to distributed, a measure based on current varying weights for different ustries is needed. This measure is probably one of the most fundatal in the application of productivity studies to wage questions, since the over-all gains in national productivity which have justified, during past century, the continued improvement in our standard of living similar over-all gains which are expected to justify corresponding rovements in the future.

he concept of gross national product is more helpful in this problem the concept of national income. Gross national product is the ary concept, since national income is derived by subtracting from s national product depreciation accruals; i. e., the capital assets osed to have been consumed. Annual depreciation accruals never very satisfactory as measures of the capital value used up per year they were never designed for that purpose, but are simply the ts of convenient and conventional accounting procedures for spreading capital costs by years. During the next few years, annual depreciation accruals, as recorded in the books of manufacturing companies, are going to be still less satisfactory measures of capital value used up since many companies are going to use, without any depreciation charges, equipment that was paid for and amortized during the war, and in addition, depreciation accruals based on plant cost will be much lower than the value of plant used up as measured by replacement cost.

A defect in both national income and gross national product is the inclusion of interest on the public debt. In the speaker's opinion, it would be preferable to consider only nongovernment output, even though it is possible to justify the inclusion of some of the government expenditures because they represent consumer services. However, most government services are not valued in the market place and the only value that can be assigned to them is the conventional one of what is paid for them.

It is important that measures of national production reflect gains through technological improvements and replacements. Natural gas will perhaps be brought to the eastern part of the country, replacing some coal. If it serves the same purpose, gross national output is increased or is maintained at less input.

In some industries, it is very difficult to consider productivity as due to the efforts of the workers immediately concerned. In the exhibition of motion pictures, for instance, there is, according to the formula, greater production per usher where the theater is filled than when there is a small audience. In fishing, again, production depends mostly on natural factors which the individual fisherman merely accepts. It is difficult to think of productivity as having anything to do with efficiency of labor and management factors in such cases.

Discussion

Duane Evans (U. S. Bureau of Labor Statistics): An illustration will show the difference in results attained by weighting with man-hours and with value added. The number of man-hours required to produce a thousand cigars decreased about 30 percent from 1939 to 1945, and the number required per thousand cigarettes decreased about 20 percent If we determine how many man-hours it would have taken in 1945 to reproduce what we actually did make in 1939, we will get a figure between 20 and 30 percent as our average. If we determine the value per man-hour in constant prices, created in these two industries together, we get 60-percent increase.

Value-added weighting is useful for some purposes but not for other One cannot conclude, on the basis of such a measure, that it is possib to increase profits, to lower prices, or to raise wages to the extent o a 60 percent increase in efficiency. The change is due partly to a shift of production from industry to industry, and no single plant in either industry is necessarily 60 percent more efficient.

For the national economy, it becomes virtually impossible to measure physical productivity and it is necessary to use the value concept. Each has its own field of use. The physical concept has a much more immediate relation to economies in the usual sense.

Solomon Barkin (Textile Workers Union of America, CIO): As suggested earlier there are sources of increased efficiency which are not reflected in the measures of output per man-hour but which are relevant to the process of trying to distribute increased productivity among the various components of our productive system. For example, in a number of industries chaotic competition has been ruinous. As a result of stabilizing controls there will be fair-trade practices. In some industries, as for example in the apparel group, the unions have contributed to greater stability, and the result of such stabilization is a diminution of the amount of capital that gets destroyed.

Another illustration is the cotton-textile industry, in which the function of selling is being integrated with the function of manufacture. The integration of these two operations will not show up in any of the figures that we have. However, it will mean a reorganization of the systems of production and designing, of fabrication, and of marketing, which will stabilize the industry and possibly result in less loss and less capital involved in the industry for the same output. In wage negotiations, the union will be tapping this economy because it will tend to show up in a higher level of profits. Another example is the tendency in the men's clothing industry for the manufacturer to have his own retail store.

Mr. Hagen: Where there is an economy in a given industry which s associated with a saving of material, without any saving of labor, a study of man-hour output in the separate industries will not reflect it. However, because of the reduction of employment in a previous industry which was producing the material, without reduction in the Nation's otal output of finished products, the economy as a whole will show uch a saving.

Concepts and Measures of Productivity at the International Level

Julius Hirsch (Consulting Economist): Professor Rostas has tried o show that for manufacturing industries as a whole, output per person mployed was roughly twice as great in the United States as in the United Kingdom, and a similar result was obtained for the textile industry by the Textile Mission. He states that it is possible that American supremacy in manufacturing is obtained only at the cost of relative inefficiency in the other four-fifths of the economy.

Comparisons made by the speaker for the year 1944[2] showed that British labor received, in dollars, approximately two-thirds of what American labor received, but purchasing power probably would not have been so far from that of American labor.

It is greatly one-sided to measure productivity only by considering output in relation to human labor hours. For national and international comparisons various other standards have been developed, especially those of net output per kilowatt-hour and net output per installed horsepower. Data from the British Census of Production for 1935 show that where there is much human labor and little machinery, net output value per kilowatt-hour is high. Where there is little labor and much machinery, the reverse is true.

A specific German approach to the question of efficiency was a systematic nation-wide comparison of costs and performances in industry. Professor Schmalenbach developed schemes for uniform cost accounting for more than 60 industries, and industry and government assisted in this work. In this way, it was possible to compare every individual cost element in a business with those in other businesses in the same industry. These methods brought about an enormous increase in efficiency. German statistics show an increase in value added by manufacture per man-hour of about 50 percent from 1926 to 1936.

In the Soviet Union, there is a decided attempt to bring about an increase in productivity with all means available to the concentrated power. Production quotas are allocated to every factory, every department, and ultimately, every laborer. The goals of the 5-year plan called for an average annual rate of increase in productivity of 12 percent in all industries, and 15 percent in the heavy industries. The Russian publications say that in most cases the performance of the Russian industry is somewhat better than the plan; the statistical evidence, as far as we have it, does not yet show how far this has been the case.

In the field of international comparisons, the first work was done on distribution—wholesaling and retailing. The great area of retailing has been neglected in the usual discussions of productivity. It is, however, probably the area where there is the greatest need for a change. The Harvard Business School has stated that the costs of distribution, including transportation, absorbed 54 to 59 percent of the total cost of producing and distributing goods. International collaboration in eliminating sources of waste has been adapted to great advantage by the members of the International Association of Department Stores. There are new attempts in the United States, as in Sweden and Switzerland, to lower the increasingly heavy burden of distribution costs, though none has as yet had decisive results.

---

[2] Mr. Hirsch's comments were based on tables on "Productivity and Productivity Measurement and International Cost Comparisons," which he had distributed to the members of the conference.

Comparison of materials, wages, overhead, and profit in the main manufacturing and mining industries for Sweden, England, and the United States in three different years at different stages of the business cycle shows that the share of materials in the total is almost identical. The share of wages is highest in England and lowest in the United States.

The best international exports we can make are those of knowledge—how the suffering nations may soon reach the level of highest productivity. We have ourselves reaped enormous profits through such exchanges. In showing others how to increase productivity, we teach them how to help themselves to better and better standards of living.

CHARLES MERWIN (International Monetary Fund): All of the difficulties encountered in making comparisons of productivity at the national level, the industry level, the plant level, and the job level arise in an accentuated form in international comparisons. The problem of index numbers is even more difficult to resolve on a spatial basis than on a temporal basis. In using broad measures, there is the difficulty of determining what exchange rates to use. Finally, differences in definition and classification usually present more practical problems in an international comparison than in a temporal comparison.

Nevertheless, a comprehensive comparison of productivity at the international level should be attempted, and the appropriate time is the present, when we can profit from wartime experience. It would be necessary to have an international working party. This working party would try to define the problem, uncover usable data, and determine differences n productivity for the economy as a whole, for particular industries, for particular products, and even for particular jobs. Finally, such a working party would appraise the strategic factors accounting for the differences n productivity.

Such a study could be sponsored on a nongovernmental basis by, say, philanthropic foundations in two or more countries, or it could be done on the governmental level. Since the Board of Trade in Great Britain has engaged Professor Rostas to study the productivity of competitor ountries, an obvious international working party would be, say, the Board of Trade and the U. S. Department of Labor. Private business nterprise should participate in such a study. Corporations which operate n an international scale should be an ideal source of information as to etails concerning productivity on the job and in the plant.

HANS STAEHLE (International Monetary Fund): The usual procedure in dealing with the question of comparisons of the change in productivity over time within one country with the change in another country, is to compute a production index, which is weighted by value added at one particular moment of time. On the other hand, the employment index usually is the unweighted, unadjusted sum of all man-hours worked.

In any kind of index-number computation it is always conducive to clarity to consider an index number as a weighted average of some variable. Since the variable usually measured is the ratio of output to man-hours, such an index gains in clarity if it can be built up as a weighted average of such ratios, and then combined into some aggregate expression.

Interpretation of the usual type of index (based on a production index weighted by base-year value added) in terms of the original industry indexes is extremely difficult and leads to a weighting system which looks at least awkward in symbols. If a weighted average of indexes pertaining to particular industries is desired, then of necessity weighting by man-hours should be used. In this case, the index is clear-cut, and its computation would not exclude such other extra measures as might be found useful or necessary for other purposes. Such an index would measure the *average* change in productivity per man-hour actually worked. The weights should be the man-hours worked currently, year for year, in each industry.

For the purpose of checking on this idea, the speaker had taken 15 out of 17 of the industry groups that Dr. Fabricant presents in his work, and had computed output per man in each one, weighting them together with shifting weights, year for year, by the number of men actually at work. Finally, an over-all and very rough correction was made for the disproportional change in total man-hours as compared to total employment in terms of the number of men.

For the period 1899 to 1939, the speaker computed from Dr. Fabricant's productivity index an average annual rate of increase of 2.98 percent. Taking the index computed with changing employment weights, the result of 1.95 percent a year—a tremendous difference—was obtained. For the period 1899 to 1929, Fabricant's index leads to an averag increase of 2.94, whereas the speaker got 1.79 percent.

The speaker by no means subscribes to the idea of a normal continuin increase in productivity. Conceptually, there is no doubt whatsoever tha there can be no automatic, virtually self-perpetuating increase in produc tivity of that sort.

Any rates of increase, over time, of productivity in a country are onl loosely related to the increases in real income as it can be measured, fo example, by deflating money incomes. Thus, if a country imports a larg part of its food supply and food becomes cheaper, real incomes wi increase. However, if that decrease in food prices is due to increased efficiency in other countries, it is one more instance of the world solidarity in greater efficiency.

Discussion

Prof. J. R. Hicks (University of Manchester, England): The more price and value are used as weights, the closer you bring the discussion to the general field of national income. Possibly the next thing which needs doing is to get the national accounts divided up properly by industries, so that the contribution of different industries becomes clearly appreciated. A good deal of the discussions at the conference have tended more in that direction than in the direction of productivity. Productivity work proper does have a further function, in the direction of trying to explain why the real national income, or contributions of particular industries to the real national income, move the way they do.

Solomon Fabricant (National Bureau of Economic Research): The differences that Mr. Staehle mentioned in the indexes of manufacturing output compiled with different weights were very much larger than those found by the speaker's own experimental computations along the same line, and it would be well for Mr. Staehle to check his computations. The consistency criterion mentioned by Mr. Staehle can be met in several ways. One way is to define the output figures for the individual industries so as to attain that consistency. An index of "net physical output," something analogous to net value added, will yield a measure for an individual industry such that when averaged for all industries the result is consistent with deflated national product. Moreover, such an index of net physical output takes into account some of the points Mr. Barkin mentioned. For example, savings in materials would result in a greater rise in net output than in the usual indexes of "gross physical output."

Charles Roos (Econometric Institute, Inc.): It would be desirable first to define the purpose for which a productivity index is to be used and then to build one to meet that purpose. Since the greatest productivity changes are in the newer and growing industries, national productivity might be the summation of growth functions and it is thus wrong to use a logarithmic function to describe productivity. With respect to costs of distribution, if the customer is willing to pay for services, it is up to ndustry to provide the service and it is not our province to say that the cost of distribution should be lowered. Finally, it is important to state very clearly how any index is constructed. If that is done, there will be a use for almost any weighted index.

E. J. Riches (International Labor Office): The ILO would welcome suggestions on means to insure that the basic data collected in different countries are as nearly uniform as possible and that methods followed in making measurements of productivity are standardized internationally. In drafting proposed international standards for employment statistics for submission to the Sixth International Conference of Labor Statisticians, which will convene in Montreal in August 1947, careful consideration will be given to the discussions of this Productivity Conference and to suggestions which members in the conference may send to the ILO.

OCTOBER 29—MORNING SESSION

Chairman, Isador Lubin, President of the American Statistical Association

Scope and Limitations of Existing Measures of Productivity

Duane Evans (U. S. Bureau of Labor Statistics) : All the participants have received a bibliography which attempts to list the main references to quantitative work in the field of productivity. The Bureau of Labor Statistics should be informed of important omissions, since the bibliography may be reissued later.

The Bureau of Labor Statistics has been working in the field of productivity since at least 1898. Its present work owes a substantial debt to the activities of the National Research Project on Reemployment Opportunities and Recent Changes in Industrial Techniques. Continuing work in the Bureau of Labor Statistics was started in 1941 with a staff of 25 people, but within the past year the number has grown to about 65.

At one time or another, the Bureau of Labor Statistics has done some work on almost every aspect of productivity. That part of its work which has probably received the most attention is the preparation of productivity indexes, or indexes of physical output per man-hour. Before the war, there was the invaluable help of a Census of Manufactures every 2 years, but such a census has not been taken since 1939. There may be one covering the year 1947, but the results will probably not be available until 1949. The census is especially valuable because it presents necessarily comparable production and employment statistics for the same establishments.

Since 1939, employment reports have been obtained from one source and production reports from others. The question of comparability between the production and labor reports presents continual difficulties The Bureau has systematically examined the statistics collected by al agencies, trade as well as government, to see whether there is any material which can be used to prepare additional indexes of outpu per man-hour, and this work will continue.

None of the indexes is perfect. It is a commonplace to the statistician
hat all figures of broad coverage include imperfections. The real ques-
on is the permissible range of uncertainty. The guide on this question
; the following: Would anyone be likely to reach a different policy deci-
ion because of errors or imperfections in the figures?

The Bureau naturally receives criticisms of its indexes and sugges-
ons for improvement. These are all carefully examined and appraised.
Ioreover, there is a substantial amount of self-examination and self-
iticism, and a continuous effort to improve the validity and field of use
productivity figures.

One of the criticisms made is that the man-hour figures include, to
me extent, hours which are paid for but not worked. If such hours
uld be excluded, the indexes of output per man-hour would be some-
hat higher. The Bureau's figures on employment and pay rolls are
t collected primarily for the purpose of computing productivity
easures. The series are in part designed so that there will not be erratic
riations in average hourly earnings. The inclusion of paid vacations in
man-hour figures tends to balance out the average hourly earnings
ures during those periods of the year when vacations are common.
may be possible that some correction can be made to exclude hours
id for but not worked, but productivity work is not the prime factor
determining what type of information is collected.

Another problem is that the employment series collected by the Bureau
based on month-to-month changes in identical groups of plants. Such
ies require periodic adjustments to a benchmark. At present, many
the series are not adjusted, and the general direction of the bias is
wnward. The speaker is more concerned about this problem than any
er single source of bias which might affect the indexes.

Several statements which had been made, to the effect that the field
use of these indexes is limited, are heartily endorsed. The indexes have
n incorrectly used, and as a result there has been criticism of the
S. It may be that the BLS has failed to qualify the indexes sufficiently,
even when extensive and lengthy qualifications are attached to an
ex, the index is sometimes stripped of the qualifications and presented
mmutable fact. For example, the Bureau has not been able to prepare
measure of output per man-hour which covers all manufacturing
ing the war period. Measures have been prepared for a limited
nber of nonwar industries, mostly those producing nondurable goods
naterials. The average for that limited number of industries has been
l in some instances to represent manufacturing as a whole. This is
use or misrepresentation.

he Bureau of Labor Statistics is compiling a brief report for each
stry for which it has published indexes of output per man-hour.

These reports will include all the basic figures, all the weights, and such analysis as can be made of the effects of various possible revisions. The BLS will send these reports to interested people in the unions and companies in the industries concerned; their criticisms and comments will be invited. No promise can be made that this will be done for all the industries, but an effort will be made to complete the task before final indexes covering the year 1946 are published.

A new program, now under way, is designed to yield for a number of industries more satisfactory measures of annual change in output per man-hour than have been available in the past, and more particularly it will give productivity measures for durable-goods industries about which nothing previously was known. In each industry selected for study, a group of products is chosen to represent the industry. Careful specifications are drawn up for each product, and a sample of plants manufacturing each product is selected. From each plant, the Bureau is attempting to secure an annual report on the average number of man-hours required to produce the specified product. The direct reporting arrangement eliminates many questions of comparability, makes productivity measuremen independent of secondary sources of information on production an employment, and permits the collection of collateral information explaining the reasons for changes in output per man-hour. The survey in each industry can be designed to accommodate the special problems an operating characteristics of the industry.

Statistics of productivity, or of anything else, are tools; they are no themselves things. Recognizing that figures are tools, it is up to us t understand them, to polish them as well as we can, and to apply them t the particular jobs which they are best fitted to do.

LIMITATIONS OF PRESENT BLS MEASURES OF PRODUCTIVITY AND LABOR COSTS

Katherine Pollack Ellickson (Assistant Director of Researc Congress of Industrial Organizations): The BLS indexes of produ tivity and unit labor costs have serious shortcomings and have expand unduly to fill the void in this important field. It is the responsibility the BLS to try to avoid this result, first, by hemming in the indexes wi a sufficient explanation of their limitations and, second, to seek to in the gap in other ways so as to present a properly balanced pictu In addition, the indexes should be carefully reviewed in order to impro them where possible, or to terminate them if they are unreliable.

The following are specific limitations of the indexes which the Burea should both seek to remove and explain fully in all releases and sta- ments:

(1) Production patterns within many industries were greatly changed y the war, so that the degree to which the output series represented ach industry undoubtedly fluctuated considerably. Government-procured ems generally were made to higher specifications and required more ork than civilian items, as for example paratroopers' boots as comared with ordinary shoes. It would seem to be incumbent on the BLS make an analysis of this matter generally available.

(2) Various systems of weighting may be used to combine the compoent parts of the production series for each industry. It would be helpful explore the effect of different bases for weighting, to indicate the ossible range in which the indexes might vary if different methods ere employed.

(3) If the employees covered in the man-hour series are making roducts not represented in the production series, then obviously errors sult. Many companies changed their products during the war but conme to be classified according to the 1939 basis in the compilation of the LS employment and man-hours data. Although the BLS dropped dexes for industries in which it knew that a considerable shift in the ture of products had occurred, no thorough canvass was undertaken in e remaining industries to make sure that the employment and man-hours gures actually matched the products with which they were compared. It should be possible to make some check for at least some of the dustries, in the same manner as attempted by Mr. Barkin for the nthetic-yarn industry. At the very least, this limitation should be menned, not just here but in all publications.

(4) The BLS employment and man-hours data are artificially inflated the inclusion of time paid for but not worked; that is, vacations, lidays, call-in time, lunch time, sickness for which benefits are paid, d so on. The BLS specifically asks the reporting firms to include in eir employment and man-hours reports all hours which were paid for t not worked. Since unions have won very marked gains along these es in recent years, a definite downward bias results. Thus, each week vacation with pay during which no work was performed adds 2 rcent to the man-hours reported for the employees affected. The BLS dustrial Relations Branch reports 2 million workers as covered by ion contracts with provisions for paid vacations in 1940, but 11½ llion in November 1944. Vacation time is only one of the types of time at are paid for but not worked. This question requires careful investition and possibly some adjustments; it could mean an error of 3 to ercent.

(5) Also, the BLS employment and man-hour series are affected by a wnward bias that results in part from delay in securing information new firms. Unemployment-compensation data are used to check BLS

employment reports for major industry groups, and some subgroups are also being adjusted by these benchmarks, but some downward bias remains. This operates to offset the upward bias in the man-hours data etc., but there is no reason to assume that the errors cancel each other out

(6) The BLS indexes of unit labor cost are derived by relating pay rolls to output per man-hour. All the errors already mentioned therefore are carried over into the labor-costs series, and some may well be compounded. The pay-roll figures include items, such as premium pay for night shifts, which are granted labor not merely because of the inconvenience to the workers but also because of the savings resulting to employers. Obviously, running two or three shifts produces savings in overhead which are likely to more than offset the premium pay, so tha including it in unit labor costs produces a misleading result.

(7) Output per man-hour as measured by the BLS is too narrow concept of productivity. Economies in production brought about by bette integration of industries, substitution of improved materials, and mo economical use of fuel and power are not taken into account. The BL should place its series in proper perspective by discussing these factor

(8) The 29 nonmunitions industries for which the BLS has issue indexes in recent years are unrepresentative of all manufacturing b cause they are industries in which the effects of the war tended impede rather than enhance productivity advances. Autos, aircraft, shi building, steel, and all the metal-fabricating industries are omitted. good many nonessential industries are covered, which suffered especial from shortages of manpower, materials, repairs, and equipment. As result, the BLS release for 1945 and earlier releases have erroneous conveyed the impression that productivity did not rise during the wa and in 1945 was only slightly above 1939 levels. Since the data ha already been released, the BLS should immediately issue an offic statement on their proper interpretation.

Although the preprint of the December 1946 Monthly Labor Revi article partly covered the speaker's proposals about interpretation of the indexes and putting them in proper perspective, the article still relied t heavily on the indexes and implied that they had a degree of accura which cannot be substantiated. All releases should carry an explanat of these limitations.

Special industry studies are being undertaken by the BLS, which follow through changes in man-hours required for specific operations production processes. This approach is worth exploring, but therei grave danger that the products of operations selected will be conside representative of the industry when they are not. The most stable opera tions are those which can be most easily studied. In areas where rai change is taking place, continuous measurement may well prove imp ble. The reporting companies know very well that labor may use the sults to seek wage increases. There will be a temptation to err on the le of understating increases in productivity, not through misrepresention of the figures so much as through selecting processes which, for me reasons, the employer may think are more representative of the lustry, but which in many ways are not.

The planning of these special studies, including the choice of operations d the review of results from time to time, should be done in consultan with union representatives. Although the BLS may be placed in the emma of making the studies on the employers' terms or not making m at all, the Bureau should take a firm stand against employer prese and should explore the possibilities of compulsory reporting of ential information.

The BLS should explore new methods of approach along lines sugted by this conference. It should offset the erroneous impression ated by its indexes of output per man-hour and labor costs by explain- the wartime factors which interfered with full development of protion potentialities. It should also stress the tremendous increases in luctivity which occurred in war industries, the vast effects that can expected from plant expansion, the significant increase in machine s with harder cutting edges, the pooling of research information, the ulation of research by the Government, the acquisition of German nts, etc.

nstead of simply assuming that the long-time trend of a 3-percent ease in productivity will continue after the war, the BLS should ilert to explore whether this long-time trend may not have been lerated by the wartime developments. Only through a broader apch can the BLS place its indexes in proper perspective and avoid the nful, even though unintentional, underestimation of the increase in uctivity in our economy.

PROBLEM OF PRODUCTIVITY MEASUREMENT IN THE SHIPBUILDING AND SHIP-REPAIR INDUSTRY

SALIND SCHULMAN (Research Director of Industrial Union of ne & Shipbuilding Workers, CIO): In peacetime shipbuilding, like locomotive production and large turbine building, is custom produc- There has not been, except during wartime, any measure or attempt asure of production in this industry. The Bureau of Labor Statistics oublished a study of productivity changes during the war, when numbers of vessels were built, but this study has absolutely no use eacetime production.

any form of custom production, certain operations remain comparatively stable over a decade or so. It might be possible to develop a series of ratios measuring operational cost as adjusted to quantity of operational production. Such a series of measures would reflect, over a short period, major technological change and improvement and major changes in labor utilization.

Rapid technological changes in phases of construction, which perhaps cannot be measured on an operational basis, could make the index for one particular operation meaningless, but if a series of common-denominator operations were developed, the limitations of any single operation might be overcome. Another limitation is that the earnings figures may be inadequate because of modifications of rate structures and modifications of the operations themselves. Continual changes in design will also invalidate this approach.

However, if a series of operational ratios is developed and used over not too long a period, valuable information may be obtained on the custom-production industries which cannot be derived in any other way.

SCOPE AND LIMITATIONS OF EXISTING PRODUCTIVITY MEASURES

ANDREW COURT (General Motors Corporation): The speaker canno agree that Government wartime research has made a large contributio to all types of manufacturing industries. It has in some areas, but it ha not in others.

In the auto industry, the poundage of product per man-hour, compute according to a crude formula developed by the U. S. Department o Commerce, showed 18½ pounds per man-hour in 1941. For 1946, th output per man-hour has been running less than 14 pounds.

It is possible to compare accurately the productivity of different ind viduals on the same job. Where the union permits, such compariso enables the employer to reward individual effort and skill. This ten to maximize the income of the workers. Comparison of different jobs a given period, or of jobs which change from period to period, is e tremely difficult or impossible. For any industry that is evolving, pr ductivity comparisons over a long time span are likely to be crude, least. In the speaker's opinion, attempts to measure or compare pla productivity are practically useless as factual tools in negotiating chang in wage levels or other union-management economic issues. The wh idea of attempting to base wage rates on productivity in a speci company or industry is inconsistent with equal pay for equal wo

Much of the change which occurs in productivity is due to for developed outside the industry in which the results appear. Ma factors in the high productivity of the American motor-vehicle indus include a large market free of tariff walls, good roads, and progress upplying industries such as rubber, steel, glass, and machine tools. nother important factor is the American ideal of free competition. ndustry-wide production planning and pricing have probably restricted ompetition and the growth of the industry in England and Europe. tandardization is also of great importance in the motor-vehicle industry. is possible because Americans are willing to buy cars which look alike. hus, it is very difficult to interpret industry productivity data.

On the national level, there is a great delusion that productive capacity unlimited and that the only problem is to provide mass purchasing ower. Actually, the farms and factories of this country have never pro- iced nearly enough to provide a fully satisfactory standard of living r everybody. For example, the amount of meat and fat and cheese quired by the BLS maintenance budget was about twice the amount at could be purchased with ration points in 1944 and 1945.

Discussion

Boris Stern (U. S. Bureau of Labor Statistics): The productivity ta published in the past by the Bureau of Labor Statistics have been tremely useful in describing, in general terms, developments with spect to machinery, increased productivity, higher wages, and shorter urs. The work the Bureau may do in the future may become more fective because it is now a more-integrated agency, it has more skills, d the need for productivity data is more generally recognized.

There is a serious danger, however, in that this new tool is being used r purposes for which it is not intended and cannot be effectively used— llective bargaining. The data hitherto available cannot be used for col- tive bargaining except in a general way for describing the history of e industrial arts or the effect of the use of machinery on our standards living.

If productivity information is desirable for collective bargaining, labor d management should agree, industry by industry, on what methods ould be used to develop such data. With such agreement, the Bureau Labor Statistics would be ready and able to work with labor and nagement in the development of the data, provided labor and manage- nt also agree that the results obtained will be acceptable irrespective whether they show a decline or an increase in productivity. Unless re is such agreement, it must be recognized that although productivity ta are useful to illustrate certain developments nationally or in various es of industries, they should not be used for collective-bargaining rposes.

Frank R. Garfield (Federal Reserve Board): The concept of pro- tion is basic to productivity measures. If the concept of production is considered in relation to the final product and the scale of living. It is clear that many factors enter into the production process. In any particular industry, materials and fuels are consumed and transposed into finished products by workers, machinery, and management. Electric-power consumption obviously is not a satisfactory measure of the whole production activity in an industry, and neither is man-hours. In the textile industry, it takes a great many man-hours to produce $10 worth of net product; in the chemicals industry, very few man-hours. For measures such as gross national product and national income, the whole community of statisticians is agreed on including all of the product and including it in value terms.

It is true that when values added are used as weights, elements of the market enter into the picture. Value is influenced by decisions of the customers as to what they are willing to pay and by the decisions of the producers as to what they are willing to receive for their services and their goods. Granted that there are elements of monopoly and of Government price fixing, the value-added figures reflect, as nearly as anything, the combined judgments of the community. Therefore value added for the most representative period for which data are available should be used as weights.

Solomon Fabricant (National Bureau of Economic Research): The National Bureau of Economic Research has published studies on productivity, production, and employment in manufacturing, agriculture, and mining, and is now working on other sectors of the economy. Its indexes are simply byproducts of these studies. The National Bureau is interested in the factors affecting the growth of our industries, or, in some cases, the decline. Studies are made not only of the factors affecting productivity, but also of the relations between trends in productivity, in employment, in production, in capital, in prices, in wages, and so on.

John D. Gill (Atlantic Refining Co.): Regarding Dr. Stern's remarks, we can use the present productivity measures in bargaining, but we need to understand that they are not accurate and to use them as approximations. Unless there is a balance between our power to produce and the ability to clear the market of that production by appropriate measures of compensation, there will be severe dislocations; thus we need to know something about the increase in production which becomes the basis for collective bargaining.

Economic measures which lack the dollar mark should be used only when it is impossible to make a report based on dollar magnitude. Because of competition, it is possible to lean heavily on accounting profit-and-loss statements which make possible a comparison of the results o any operation with the operations of comparable firms elsewhere.

If the general change in production—either gross national product or national income—is used to measure the general change in compensation, there remains only the problem of administration. A 10-percent increase in wages in a mass-production industry may be possible without an increase in prices, but a 10-percent increase in wages in a firm hand-tooling belts, for example, may require an increase in prices and may result in the loss of the market. We should anticipate such changes and prepare either to substitute machine-worked belts for hand-worked belts or go out of business.

MARTIN GAINSBRUGH (National Industrial Conference Board): One desirable result of the conference might be that the BLS prepare a reply to the CIO criticisms of the BLS indexes of productivity.

CELIA STAR GODY (U. S. Bureau of Labor Standards): The ques-
ions raised by Mrs. Ellickson concerning the BLS productivity indexes
night be separated into three categories. The first question is whether
he measures are correct for what they are intended to show. It is agreed
hat the indexes are not correct to the last decimal place, but many of
he factors mentioned are much less significant than they are generally
elieved to be. For example, on the question of the time paid for and
ot worked, if every worker had a 1-week vacation, there would be
n error of something less than 2 percent in the man-hour series. The
ctual average is doubtless considerably less, since many workers are
ot covered by vacation provisions, many who are covered have not
orked long enough to be eligible, etc. The error in the man-hours
ndex is the difference between the extent to which there are paid vaca-
ions in the base year and the extent to which there are paid vacations
n the year under consideration, and may be in the neighborhood of 1
ercent. When there have been more significant changes in the reporting
f man-hours, the BLS has made explicit adjustments; for example, in
oal mining, for which, after the change to portal-to-portal pay, the re-
orted hours figures included travel time.

It is true that there have been, in many industries, changes in the
ecifications of products, new types of goods, and changes in the pro-
ortions of different products. The BLS has not continued to show
dexes for those industries in which such changes were so great that
was impossible to make any comparison. For the remaining indus-
ies, the Bureau attempted to learn all it could about the changes in
e nature of the products and to make tests of the accuracy of the pub-
shed indexes. For example, it has been stated that the index for the
oe industry is too low, since military shoes are bigger and heavier
d presumably better than civilian-type shoes. The information ob-
ined indicates that the military work-type shoe does require more

labor than a civilian work-type shoe, but less labor than a civilian dress-type shoe. If the index is reweighted to take this factor into account, the result differs by only 2 percent from the published figures.

In cases in which the indexes incorporate weights for some old period, tests have been made, changing the weights to the year 1939. In practically all cases, this reweighting has resulted in only small changes in the indexes.

Two problems raised by Mrs. Ellickson—the possible bias in the employment series, and the comparability between the production and employment series—cannot be solved completely until there is another census. Many of the industries for which indexes are shown are fairly well defined and it is possible to state with confidence that the indexes include their total production and that the production figures are comparable with the employment series. In other cases, varying amounts of products are not included in the production series and there is no information on whether there has been any shift in the importance of such products. A complete evaluation cannot be made until there is another census; until then, all that is possible is to determine from available sources whether there is any indication of such shifts.

A second question concerns the factors which make the indexes go up or down. These are not limitations, but rather explanations, of the indexes. For example, where there are special wartime factors which make for declines in some of the indexes, it is important to know them, not because the indexes are not good measures but because it should not be assumed that the wartime levels will be the levels in the future when those factors have disappeared. In the building-materials industries, for example, there were substantial drops in output per man-hour during the war simply because of the decline in production. It is important to know the reason, because it can definitely be expected that as soon as production increases, output per man-hour will also rise. This has actually happened during 1946.

A third question is what additional measures would be desirable. Output per man-hour is only a partial measure; the ratio of output to man-hours in itself does not give a complete story of what is happening in the economy. For example, data on unit labor cost must be used together with other information. It is necessary to consider changes in costs of materials, in overhead, and in all the factors which enter into the cost structure. The Bureau would like to do as much as possible in the way of providing additional measures of productivity in this broader sense. Whether it can do so depends, first, on the availability of information on these other factors — materials, overhead, etc. — and, secondly, on the availability of staff for such work.

Duane Evans: Mr. Garfield's comments on the desirability of weight ing with value added were probably based on his experience with the Federal Reserve index of industrial production. Conceptually such a measure tells us what the value of our production would be, relative to the base period, had there been no changes in the prices paid for all factors used in production, including labor. The speaker knows no better method of measuring the general level of industrial activity than the one used by the Federal Reserve Board.

In the use of man-hour weights, there is an attempt to answer a different, clearly stated problem: If we were to reproduce the physical amounts produced in some base period, how many man-hours would it take relative to the man-hours used in the base period? This physical approach is useful at the plant and industry level. The bigger the sphere encompassed, the less the utility of this approach because the necessary figures cannot be obtained.

It is believed that the other points which have been raised will be met by the analyses of the indexes which will be sent to the interested parties, and that these statements will also answer Mr. Gainsbrugh's point.

OCTOBER 29—AFTERNOON SESSION

Chairman, Thomas Blaisdell, U. S. Department of State

Need for Additional Productivity Measures

Lazare Teper (International Ladies' Garment Workers' Union, AFL): The significance of the physical output man-hour ratio will be examined, first under a set of theoretically controlled conditions and then under conditions complicated to bring them into relation with reality.

First, consider a single plant which turns out a single product and assume that the product manufactured by this plant did not undergo any changes in its specifications; that the raw materials used remained similarly unchanged; and that there were no changes in any of the manufacturing methods or equipment. Under such conditions, variations in the physical output/man-hour input ratios can be interpreted as indicators of changes in the relative average efficiency of the labor force. Of course, the ratio does not, in any way, throw light on the causes responsible for the changes.

Next, assume that the theoretical plant changed its methods and techniques of internal operations (including installation of different capital equipment). Since the factors responsible for changes are no longer exclusively on the labor side, this concept of efficiency changes must be deemed a function of the many independent and interdependent forces which take labor, management, and equipment into account.

If the specifications of the product turned out by the plant have also been evolving, the ratio of physical output to man-hour input will reflect not only the changes in efficiency, but the effect of changes in the specifications of the product as well. When additional factors are permitted to influence the quanta of the physical output/man-hour input ratios, the meaning of the resultant statistics is complicated to an even greater extent. Thus, the nature of integration between the productive processes of a given plant and those of its suppliers and customers changes over a period of time, and such changes either increase or decrease the need for workers. Similarly, changes in the specifications, character and nature of raw materials may also affect the plant's worker requirements. As long as it is impossible to segregate the various factors which may be responsible for the fluctuations in the physical output/man-hour ratios, the designation of such ratios as measures of productive efficiency seems hardly tenable.

On the other hand, a statistical series showing the ratios of man-hour input to physical output does serve as an indicator of manpower utilization—measured in units of time input—within the confines of a particular plant, needed to turn out a unit of product by changing specifications under the conditions of changing efficiency of the various factors of production and of changing position of the plant in the economy. These conclusions apply equally well to a group of plants manufacturing a single article.

If a plant is engaged in the production of two or more commodities, the meaning of the data is further affected by the inability to combine noncommensurate entities without converting them into some other quantities, commensurate with each other as a matter of statistical convenience. Thus, the technique recommended by the National Research Project and the Bureau of Labor Statistics permits the computation of a combined index for a group of products by weighting "manpower utilization" figures for the individual commodities by the units of physical output for some preselected "weight" base year. An index so computed for more than one product, in accordance with the NRP-BLS techniques, should be described in terms which denote its significance as an index of manpower utilization (measured in units of time input) needed to produce "weight" base-year units of physical output, as influenced by changes in the product specifications, efficiency of the different factors of production, and the nature of the plant's (or industry's) relationship to the economy.

The theoretical advantage of an index computed on a fixed-weight base lies in the fact that it measures but a single element of change, to the exclusion of others. Yet, in this case, there is the infusion of many factors, each of which changes in time. As long as such influences are not eliminated, one can properly raise a question as to whether an index number, which would incorporate in its make-up the effect of all of the dynamic changes which affect the economy, including changes in the relative importance of the different products, would be of greater significance for economic analysis. Such an index would reflect changes in the relative importance of the different products in the course of time, and would permit the inclusion of new products as they make their appearance. It could be described, in terms of its significance, as an index of manpower utilization (measured in units of time input) needed at different times to produce a unit of physical output in accordance with specifications, efficiency, and nature of economic organizations at each of the periods under consideration.

Since "productivity" indexes do not portray changes in productive efficiency, their designation as such should be abandoned and full qualifications made as to their meaning at the time of publication. At the same time, it would seem desirable for the investigators of productive efficiency to direct their attention, to a greater degree than heretofore, to the collection of descriptive information which is a necessary prerequisite before refinements in the productivity measures are attempted on a large scale. Research should be undertaken on the plant level to find out, in greater detail, how changes in productive efficiency are brought about and the influence thereon of machinery, management, individual effort, flow of work, demand for goods, specifications and variety of product, nature of raw material, and so on. Such studies should investigate how changes within the plant affect the skills and composition of the labor force, and what displacements, if any, changed methods of production bring. Statistical investigations, dealing as they do in averages, may actually conceal the full importance of such changes.

More information is needed about the effects on workers of management pressure for higher output, and the necessity for earning a living. Are there socially desirable optimum levels of human effort beyond which it is undesirable to go? What is the effect of the existing methods of ncentive payments on the workers' well-being? What is the effect of management's behavior on the efficiency of workers and the enterprise?

More information is needed on the influences, from outside the plant, on its productive efficiency. To what extent do changes in the demand for goods or competitors' activities induce variations in the production methods? How rapid is the process of change as between the different plants? What is the relation between capacity output and productive efficiency? How is productive efficiency affected by changes in the naure of integration between the plant and other businesses? What is he effect of developments in the field of communications and transportation on the plant?

The present interest in the question of productivity stems from a universal desire to find the clue to a better standard of living. If it is held that the answer lies in greater productive efficiency, there is no question but that econometric studies must be supplemented by investigations of cause, effects, and byproducts of such change. It is to this area that the attention of investigators of productive efficiency must turn.

In making studies at the plant level, it is particularly important that such plant studies be undertaken by an impartial agency such as the Government, with joint cooperation of advisory groups representing both labor and management.

(Mr. Teper presented an additional paper criticizing the formula used by the Bureau of Labor Statistics in computing its indexes of unit labor cost. The paper indicated that the appropriate weights for a production index to be used in deriving unit labor cost were pay rolls per unit of output and not man-hours per unit.)

Presentation of Productivity Measurements

Solomon Fabricant (National Bureau of Economic Research): The speaker, in behalf of those who produce productivity measurements, believes they must do the best possible job of presenting such measurements. They should continue to review terminology and should define terms. They should make clear what the figures mean and note some of the things they do not mean. They should be explicit about the sources of the data, about accuracy, about limitations. They should note the methods of combination, the weight systems, the weight-base periods. They should compute alternative measurements and publish them now and then, if only to dispose of questions concerning the importance of the difference between them and the figures issued regularly. They should have a base book, revised and expanded every so often, to which they can refer in the shorter public statements.

They should call attention to the representativeness and homogeneity of their samples. When the samples are not homogeneous, they should avoid combining the individual items into an average. When an average for a homogeneous group is prepared, but the group is not representative of the whole of which it is a part, they should avoid implying that it is.

When they don't know, or are not sure, they should say so clearly and emphatically. Whenever they revise, they should spell out the reasons for the revisions, and the uncertainties still remaining even in the new figures. They should dissociate questions of fact from matters of policy. They should dissociate guesses about the future from statements about the past.

It is hoped that the consumers of productivity data really read the notes and textual qualifications and refer back to the more-extended discussions provided before raising questions; that when they think of a reason why the figures *might* be off, they won't jump to the conclusion that they are in fact off, or if off, that the error is always and *necessarily* important.

Producers of productivity data welcome questions and suggestions, but hope that such questions and suggestions would not be made, at least in the first instance, via the public press. They have a weakness in particularly liking constructive suggestions.

All of us must have some common meeting ground, if our kind of economic and political system is to survive. Established fact is an essential ingredient of this common meeting ground. There are enough differences dividing us on which it is not easy to come to common agreement. Facts need not be among them. Our fact-finding agencies should be kept nonpartisan, for our mutual advantage.

From the discussion, during the conference, of the limitations of the BLS indexes of output per man-hour, it is feared that some people may get the impression that these indexes are of little value. That impression would be quite wrong. The indexes for the period since 1939 cover only a few industries. It is true, too, that they are subject to adjustment when he censuses come out. Indeed, like all statistics, they are surrounded by a margin of error. This does not mean, however, that BLS indexes re subject to so much error that they are worthless. On the contrary, for the industries to which they relate and which they are intended to over, they convey useful and valuable information.

Discussion

Irving H. Siegel (U. S. Veterans Administration, formerly with the National Research Project and the Bureau of Labor Statistics): Conumers of productivity statistics have apparently expected too much, r have ignored the cautions accompanying such measures as long as the ndicated changes conformed to their intuitions or interests. Though the vailable indexes are probably the best that can be made with available ata, they have outstanding limitations which must be taken into acount especially if they are used beyond their original purpose. In any ase, the differences concerning the definition and measurement of productivity do not seriously impede solution of the important practical roblem which motivates much of the theoretical discussion, namely, the naximization of output, however defined, of a given work force through the improvement of production processes and of labor-management relations.

George Brown (United Association of Plumbers and Steamfitters, AFL): Labor people want to see accurate productivity figures developed and want those figures to reflect efficiency. The study of productivity can occur at two levels—first, in the area of academic interests, in the development of industry and national figures; and, second, in the area of practical application, at the plant level. Enough deficiencies have been pointed out to indicate there is a large area for work at the plant level.

Lyle Cooper (United Packinghouse Workers of America, CIO): The speaker's union has not found the BLS index for slaughtering and meat packing good for bargaining purposes. The index is computed by weighting with fixed prices. The Federal Reserve index, which is on a 1935-39 base, shows that man-hour output went up substantially more after 1939 than the BLS index indicates. There is a good reason for using several years as the base period, particularly in meat packing, where prices of the different products fluctuate considerably. Between 1944 and 1945, the BLS index went up about 9 points, but a company negotiator pointed out that this change was due to the fact that hog slaughtering had decreased and beef (which is higher priced) therefore received a greater weight. The BLS itself has indicated in correspondence many limitations of the type described.

Henry B. Arthur (Swift & Co.): The explanation of the change in the BLS index for meat packing is the fact that BLS uses the total value of the product as weight, rather than something approximating value added. This gives importance to the two species—beef and hogs—which represent the total input of the farmer as well as the packinghouse worker. Between 1944 and 1945, there was no change in the total weight produced, but there was a decline in the amount of work to be done because pork production, which requires a great deal of processing, declined.

In the presentation of productivity ratios, we have conventionally shown a ratio in which the whole (production) is divided by the part (man-hours), and this convention has occasionally led us into thinking in terms of labor productivity. If a series of ratios is prepared, with the various inputs in the numerators and the output in the denominator. one might say that the relationship which changed least from one year to the next was probably the factor which most nearly accounted for the change in production. As an example, assume that man-hours per unit of product decreased 20 percent and the amount of all the other input factors per unit decreased 20 percent except power, with the kilowatt-hours used showing no change. As a first step it might be preımed that the increase in production was a result of the application kilowatts. These ratios show that it was something other than the ctor in the numerator that caused the change in the denominator.

In working with measurements, we are operating within a part of the tal field. Even the broadest measures omit about a third of our total onomy—the output in households. From a social point of view, there ould perhaps be an appraisal of the total values of our economy.

SOLOMON BARKIN (Textile Workers Union of America, CIO): The ıphasis which originates from the collective-bargaining process and om the study of national incomes is on the desirability of obtaining ɔre all-embracing mathematical techniques for gaining insight into creased productivity. It is also necessary to evaluate the importance our neglect to use some of our resources—both capital and labor— d the importance of that part of our output, such as that of houselds, which is not converted into monetary business terms. Perhaps ıat is needed is an assimilation of the concepts of measurement of ysical output with some of the concepts in the national income field, ıs some approach on the problems of untapped resources and unɔped manpower.

MARGARET SCATTERGOOD (American Federation of Labor): The AFL mbers met during the noon period and made unanimous recommendans on two points: (1) They wish to emphasize the importance of the e-study method and to urge its use, with representation of unions and nagement on committees cooperating with the government agents.) They believe the work of the conference should be continued through continuing committee on which labor, management, and government represented. They would like to refer to such a committee the quesn of whether a set of figures for the economy as a whole can be deoped and, secondly, the problem of defining or perhaps changing ne of the specifications of the present Bureau of Labor Statistics exes.

EVERETT HAGEN (National Planning Association): One of the reas for dissatisfaction with the use that has been made of productivity a is failure to agree on the meaning of the term "productivity." In nomic theory, the term means the contribution of a particular factor production; statisticians in the field use the term simply to refer to put per man-hour, whatever the reason for the change. Another diflty arises in the use of data covering more than one product. Such index can change simply because of shifts in the proportion of the nmodities, depending on the weights used. We should not criticize figures because we are not sufficiently mathematically trained to unstand them, but should realize that a figure cannot be all things for all purposes and a technician is required for its proper use. A third difficulty is the inadequacy of the figures because of failure to take account of all relevant circumstances.

The conference should create a continuing smaller body to continue to examine the existing productivity series, to clear up misunderstandings, and to investigate changes which might be desirable for new purposes.

Hiram Davis (University of Pennsylvania): It might be more productive to develop a series of ratios relating various input factors to output than to attempt to measure total input. The conference might consider whether it would be worth while to form working parties in some of the industries in which there is disagreement over how output should be measured.

Duane Evans (U. S. Bureau of Labor Statistics): Even the most precise productivity figures are not necessarily a definite guide to the way in which the production economies of the system can be divided. In the long run, output per man-hours has been going up, but there are segments of the economy in which productivity has not increased, such as some of the service industries. It cannot be maintained that wages should not increase in such an industry if, over a period of time, general earnings have gone up. If society wants the products, it has to pay a high enough wage to keep people in that industry. On the other hand there are some industries, such as rayon, in which there have been extremely rapid increases in productivity. If wage levels in such an industry were increased accordingly, it would be necessary to have a guil system to keep people from entering the industry, because wages woul be so much above the general level.

Mr. Barkin: Those who suggest the need of data for collective bargaining certainly do not have the ideas imputed by Mr. Evans. To pos these theoretical alternatives does no service to the discussion of th problem, but bars constructive thinking in this field. The problem is t get a measure of productivity, so that the parties can then rationall discuss and possibly bargain about the methods of distributing the gain

H. H. Bookbinder (Amalgamated Clothing Workers of Americ CIO): The speaker represents the workers in the shirt industry, whe the union expects wages to rise in the future, but hopes that productivi as affected by worker effort will decline. Mechanization seems to ha reached its maximum limit, and the rate of production of a shirt d pends mostly on the fingers of the operator and not on the machi itself. Because of the piece-rate structure of the industry, the work has driven herself beyond reasonable human levels in an attempt crease her earnings. On one important operation, for example, the p stitch on the collar, a girl may work on as many as two to three ousand shirts a day. This type of work has led to countless cases of ıysical and psychological breakdown. In the future, it is expected, of ourse, that general productivity in American industry will continue increase. Shirt workers should benefit from this general increase. owever, it is hoped that some decent production standards can be reed upon for industries like the shirt industry. As for sharing the nefits of increased productivity, there will be times when labor will k for the extra share at the plant level, at times the industry level. the long run, however, it must be the economy level, either in the rm of generally higher wages or generally lower prices.

Ewan Clague (U. S. Commissioner of Labor Statistics): A governent agency can do effective work in studies of individual plants or os, but only if there is general management-labor agreement on such udies. Such data, while valuable locally, have very little significance tionally. On the other hand, the general indexes were not necessarily awn up for collective-bargaining purposes. When any of them are ed for specific purposes, they should be reexamined to see if they ll fit. It is hoped that some of these measures can be made useful for lective bargaining, at least for a first approach.

Summary of Conference

Samuel H. Thompson (U. S. Department of Commerce): The conence has been made up of people who believe in progress, in imovements, in the continued movement upward of the human race and our own industrial civilization and of the United States. The conees have agreed on several major areas.

The first is that, since it is desirable in the interests of all of us to rease productivity, measurements are needed that will help find out v to increase it. We need measures adapted for use as tools in the lysis of the productive process that will help us improve the total ntity and quality of production. We need many different kinds and les of tools. We certainly need physical measures of productivity, ed on physical production and the number of man-hours or manrs. We also need monetary measures. There are many other meass we need—for example, kilowatt-hours per unit of output, pounds coal per kilowatt-hour, etc. The conference has agreed that we must clear as to what the measures we use mean and what they are useful . In index numbers, we necessarily put together things which are not mensurate; we have to use index numbers, but must not forget that . Speaker after speaker has emphasized the need for a clear understanding of the purpose and then a careful design of the instrument. At the same time, it is interesting to note how amazingly few people are keeping systematic records from which the tools could be forged.

It has also been emphasized that we need to do a better job with what we already have. The conferees have agreed that we use these measures to analyze the factors that enter into production. It has been emphasized that there are many factors which affect production and productivity.

The conferees have also agreed that the ultimate responsibility for improvement in productivity or production cannot be assigned to any single factor. The technological progress of our industrial civilization arises from the whole of our society, perhaps the whole of mankind. Mathematically, every individual of the race contributes in some measure, to either his own generation or the next. We can improve our performance, and ultimately we all gain from each man's individual effort.

There are other areas which were omitted or in which there was some disagreement. One is the matter of the use of indexes in collective bargaining. There has been general agreement on the need for further analysis leading to the design of better tools for specific use in reachin collective bargains. The conference has not discussed very thoroughl the need for both physical and monetary indexes and therefore physica and monetary weights. It has not discussed at any length the actua techniques that are available or should be devised for getting the basi data.

The executive committee wishes to announce that there will be transcript of the meeting available for inspection, but there will be n attempt to make it generally available. A summary will be prepared b the executive committee which will be sent to all the participants, fc their approval or correction, which may later be published.

The executive committee will, if the conference approves, meet an discuss ways and means of continuing the work of this conference— whether through subcommittees, through recurrent meetings of th size, or through a combination of these and other means.

UNITED STATES DEPARTMENT OF LABOR,
BUREAU OF LABOR STATISTICS,
Washington, D. C., May 7, 1947

The SECRETARY OF LABOR:

I have the honor to transmit herewith the annual report on union wages and hours in the baking industry, July 1, 1946.

This report was prepared in the Bureau's Wage Analysis Branch by Herbert M. Abowitz, under the direction of Donald H. Gerrish.

EWAN CLAGUE, *Commissioner.*

Hon. L. B. SCHWELLENBACH,
Secretary of Labor.

Union Wages and Hours in the Baking Industry

July 1, 1946

Summary

Hourly wage rates for union bakery workers in 70 cities on July 1, 1946 averaged $1.00, representing an advance in basic wage rates of 14.6 percent or 13 cents since July 1, 1945. Among the various branches of the industry the highest average was registered by Hebrew-products bakers ($1.65); the lowest by workers in establishments producing crackers and cookies ($0.75). Nine of every 10 workers received a wage increase with a majority of the workers receiving 10 to 20 percent above 1945 rates. Hourly rates in the industry ranged from $1.97 for first hands and foremen in New York City Hebrew-products shops to $0.375 for South Bend hand shop helpers.

Almost 8 of every 10 members worked under agreements stipulating a straight-time workweek of 40 hours. Overtime clauses providing time and a half for operations beyond the straight-time workweek covered 98 percent of the workers tabulated. Vacation clauses providing 2 weeks after 1 year of service covered over a fourth of the union members and an additional fourth were covered by agreements calling for 1 week after 1 year and 2 weeks after 5 years of service.

Scope and Method of Study

This survey is one of a series of annual Nation-wide studies, conducted by the Bureau of Labor Statistics since 1907, of union wage rates and related matters in various industries. The number of cities covered, ranging in population from 40,000 to over a million has been gradually increased from 39 to 75 in most of the industries. In the July 1946 survey in baking, usable data were obtained for 70 cities.[1]

---

[1] The current study is based on wage scales and related data obtained directly from local union officials in 70 of the 75 cities surveyed by field representatives working out of the Bureau's regional offices. These scales cover approximately 64,228 bakery workers. Bread and cake hand shops comprised 12.3 percent of the total membership tabulated, bread and cake machine shops, 57.6 percent, pie and pastry shops, 3.0 percent, Hebrew baking shops, 7.5 percent, other specialized baking shops, 2.1 percent and cracker and cooky shops, 17.5 percent.

These cities are located in 40 States and the District of Columbia. The rates reported for the various trade classifications are union scales in effect on July 1, 1946. A union scale may be defined as a minimum wage rate or maximum schedule of hours agreed upon through collective bargaining between employers or their associations and trade unions. Individual rates in excess of the contracted minima, which are frequently paid for long service, special qualifications, personal or other reasons, were not used in the preparation of this report.

Prior to 1939 only one classification—bread baking—was included in this study. In 1939, the survey was expanded to cover all occupations in all types of baking except delivery drivers and plant-maintenance workers. Since 1941, the data presented have been segregated by type of baking involved; e.g. hand shop, machine shop, pie and pastry shop, cracker and cooky shop, Hebrew baking and other specialized baking such as French, Polish, Bohemian, Scandinavian, Spanish and Italian.

Trend of Wage Rates and Hours [2]

TREND OF HOURLY RATES

The index of union hourly wage rates (table 1) for bakery-trades workers in the 70 cities studied as of July 1, 1946 rose to 141.6 (1939 = 100), representing an increase of 14.6 percent (or about 13 cents an hour) since July 1, 1945. The most marked improvement in basic scales—20.1 percent (about 22 cents) was registered by the specialized baking branch and a substantial gain—18.1 percent (14 cents) was indicated for the pie and pastry group. Two branches, Hebrew baking (9.8 percent or 15 cents) and crackers and cookies (13.5 percent or 9 cents an hour) recorded increases below the over-all average for the combined trades. During this same period, the Bureau's index of consumer's prices increased by slightly over 9 percent.

Increases in basic scales were obtained by all the members engaged in specialized (National) baking in all seven cities in which the trade was active.

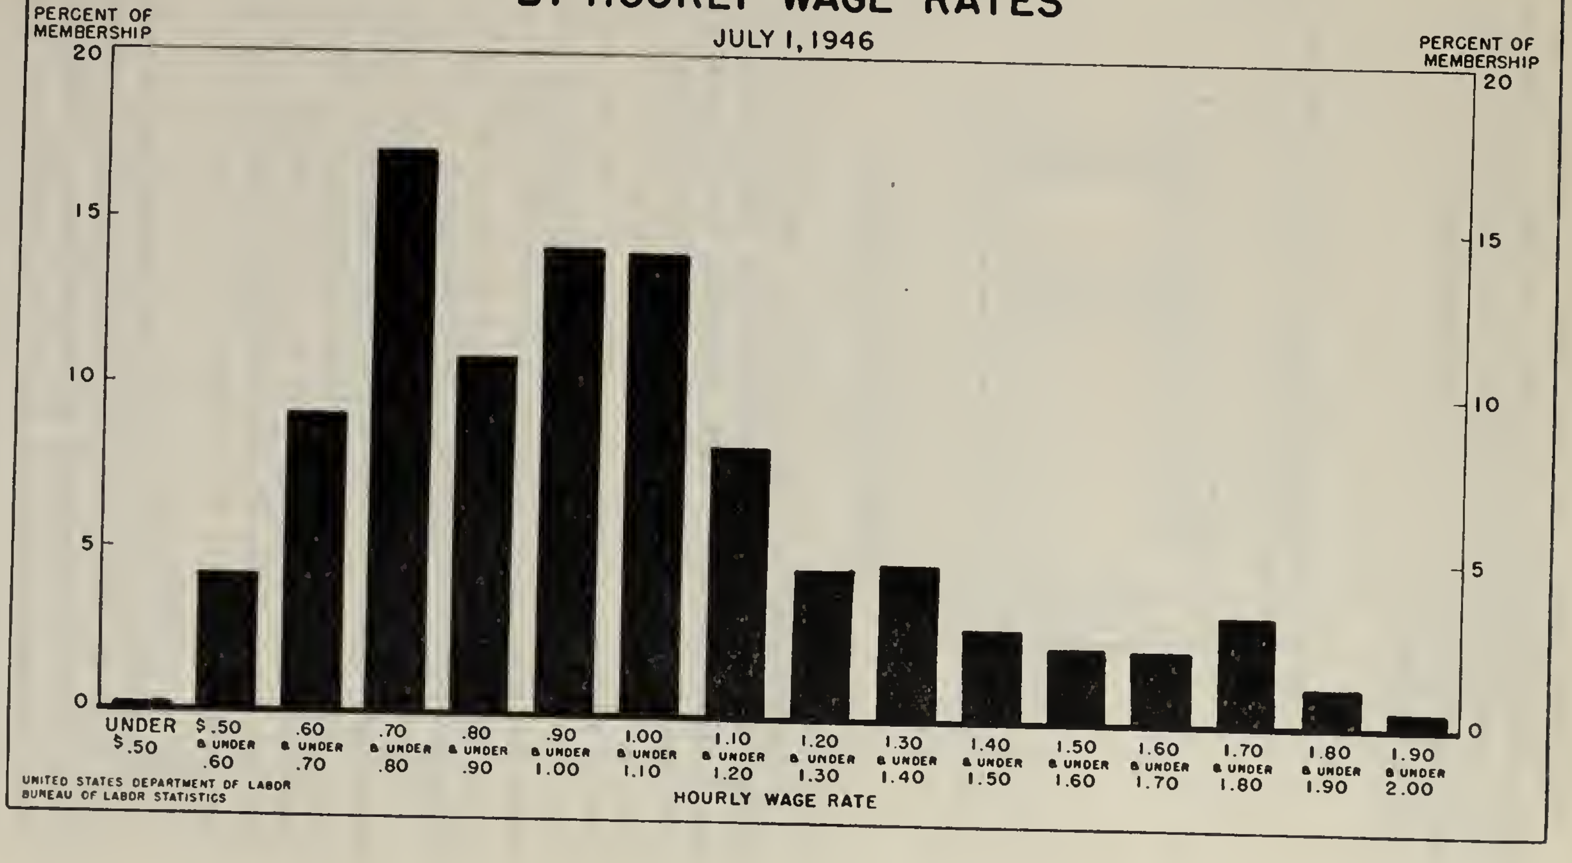
Basic hourly scales in the organized baking trades have shown constant improvement since 1939. Substantial rate betterment was registered in the interval between 1941 and 1943 (14.2 percent).

---

[2] In computing the index series (1939=100) which indicates the trend of wage rates, the annual percentage change from year to year is derived from aggregates of union quotations for identical classifications in two successive years. The membership weights in both of the aggregates used for each year-to-year comparison are those reported for the second year. To obtain the index for the current year, the total of the current aggregates is divided by the previous year's aggregates and the ratio thus obtained is multiplied by the previous year's index number. The indexes are computed on this basis in order to minimize the effect of changes in union membership which might obscure the real changes in wages. The index series, rather than the actual averages of rates in this and previous reports, should be used to determine the trend of hourly wage rates. Changes in coverage and shifts in union membership distort a direct comparison of average rates in two periods.

DISTRIBUTION OF UNION BAKERY WORKERS BY HOURLY WAGE RATES

JULY 1, 1946



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

TREND OF HOURS

The average straight-time workweek decreased by 0.3 percent during the study period. Between 1939 and 1942 the index of weekly hours reflected a gradual reduction in the workweek. From 1943 to 1945 hourly changes were not of sufficient weight to effect any movement of the index.

TABLE 1.—*Indexes of hourly wage rates and weekly hours for the baking industry, 1939-46. (1939=100.)*

Year	Wage rates	Hours
1939	100.0	100.0
1940	102.7	99.5
1941	106.1	99.2
1942	116.3	99.1
1943	121.2	98.6
1944	122.0	98.6
1945	123.6	98.6
1946	141.6	98.3

Average Hourly Wage Rates [3]

Wage rates for union bakery workers averaged $1.00 an hour in the 70 cities surveyed on July 1, 1946 (table 2). The highest trade average was indicated for the branch producing Hebrew products ($1.65). Averages exceeding the combined average for all branches of the trade were recorded for bread and cake hand shops ($1.24) and other specialized baking establishments ($1.32). Cracker and cooky bakers obtained the lowest average wage ($0.75) due mainly to the influence of the low wage rates prevailing in the unskilled occupations (such as female wrappers and packers) who make up a significant proportion of the workers in this branch of the industry.

Over 44 percent of the bakery workers tabulated reported rates of at least $1.00 an hour in contrast to 26 percent in this category on July 1, 1945. Although 31 percent of the members reported rates ranging between 50 and 70 cents last year, only 14 percent remained at this level by July 1, 1946. On the other hand, 32 percent of the workers were in the $1.00 to $1.40 brackets in 1946 as compared to 18 percent in 1945.

Better than 7 of every 10 Hebrew bakers had hourly rates of at least $1.60. A third of this group reported rates between $1.70 and $1.80. Well over a majority of the members in specialized shops received between $1.20 and $1.40, and in the cracker and cooky branch

---

[3] The averages appearing in this report were based on union scales weighted by the number of union members actually employed at each individual rate.

TABLE 2.—*Distribution of union members in the baking trades by hourly wage rates, July 1, 1946*

Type of baking	Average rate per hour	Percent of union members whose rates (in cents) per hour were—															
		Under 50 cents	50 and under 60	60 and under 70	70 and under 80	80 and under 90	90 and under 100	100 and under 110	110 and under 120	120 and under 130	130 and under 140	140 and under 150	150 and under 160	160 and under 170	170 and under 180	180 and under 190	190 and under 200

[1] Less than .05 of 1 percent.

about the same membership proportion had hourly rates ranging from $0.60 to $0.80. Almost three-quarters of those engaged in bread and cake machine baking and in pie and pastry baking received between $0.70 and $1.10, while about two-thirds of the bread and cake hand workers had scales ranging from $1.00 to $1.40.

The lowest rate reported, 37.5 cents, covered hand-shop helpers in South Bend, Ind., while the highest rate tabulated covered foremen and first hands engaged in Hebrew baking in New York City ($1.97 an hour). The latter branch, reporting active members in 18 cities, constituted 7.5 percent of all workers studied. Approximately 65 percent of the Hebrew branch membership is concentrated in New York City.

Changes in Hourly Wage Rates, 1945–1946

Better than 9 of every 10 organized workers in the baking industry for whom comparable wage data were available for July 1, 1945 and July 1, 1946 registered increases in basic rates (table 3). A majority of those receiving increases reported advances of between 10 and 20 percent. This represented a substantial change since the previous survey (July 1, 1945) when but a fifth of the bakery workers recorded wage increases which, for the most part, amounted to less than 10 percent.

Although all of the workers tabulated in the Hebrew and the other national products branch (such as Italian, French, Scandinavian, etc.) reported wage increases during the year, the extent of the increases varied among the branches. Over three-fifths of those in Hebrew baking received rate gains of less than 10 percent and very few had advances of 20 percent, whereas practically all of the union workers in other national baking registered gains of at least 10 percent, with a majority securing increases of 20 percent or more. Of those reporting increases in the bread and cake hand shop branch, a majority did not improve their basic rate position by as much as 15 percent, but almost a fourth had increases of 25 percent or more. Two-thirds of those obtaining rate advances in the machine shop branch received raises of at least 15 percent, with a majority receiving less than 25 percent. Increases ranging from 10 to 20 percent were received by the largest individual membership aggregations in both the pie and pastry branch (50 percent) and the cracker and cooky branch (57 percent).

TABLE 3.—*Percent of union members covered by changes in union wage rates and extent of increases, July 1, 1945 to July 1, 1946*

Type of baking	Percent of members affected by wage rate changes of		Percent of members affected by wage rate increases of—							
	No change	Increase	Less than 5 percent	5 and under 10 percent	10 and under 15 percent	15 and under 20 percent	20 and under 25 percent	25 and under 30 percent	30 and under 35 percent	35 percent and over

Post Survey Rate Changes

Available data concerning wage changes effective after July 1, 1946 for union bakery trades workers are limited. Several contracts in New York City negotiated prior to the survey date, covering certain categories of bread and cake hand-shop bakers, provided for automatic increases of 50 and 75 cents per day beginning in 1947. Increases in basic rates of over 30 cents an hour for first hands and over 40 cents for second hands have been reported in one establishment in that city. Peoria hand-shop workers received a $10 weekly raise, amounting to 20 cents an hour. In Philadelphia a substantial number of machine bakers were reported to have gained 18.5 cents an hour. Advances of 15 cents an hour were reported for Worcester machine-shop workers and York cracker and cooky members. Pie and pastry bakers in York and cracker and cooky workers in Toledo benefited by a 5-cent addition to July 1, 1946 rates.

Average Union Rates by City and Percent of Change Over Previous Year [4]

RATES BY CITY

The Hebrew baking branch averaged the highest rates in the industry in 17 of 18 cities reporting scales for this type of operation. The highest city average recorded for any of the bakery groups was that for Hebrew products bakers in New York City ($1.73 an hour). Bread and cake machine shop baking, the largest branch in the industry from the standpoint of employment, revealed a substantially lower trade average ($0.94) than either the Hebrew or hand shop branches. This was mainly due to the inclusion of relatively unskilled workers engaged in routine icing, packing, wrapping, and decorating operations who represent a large proportion of the labor force of this branch. Butte ($1.22) had the highest city average for machine baking and 23 other cities exceeded the branch average. In the pie and pastry branch, San Francisco, with an average of $1.44, was far ahead of the second top city, Los Angeles ($0.96) as well as the three other cities with higher averages than that of the branch ($0.885). Detroit, which for some years past has registered the highest average in the other national baking branch, maintained its top position with an average of $1.425. San Francisco ($0.990) headed the cracker and cooky branch, whose comparatively low average ($0.751) also reflected the inclusion of a substantial proportion of wrapping and packing workers.

PERCENT OF CHANGE BY CITY BETWEEN 1945 AND 1946

Newark (33 percent, about 30 cents an hour) and Rock Island district (30 percent or 22 cents) reported the highest relative increases in the bread and cake hand shop branch between July 1945 and July 1946, while in the machine shop branch, Grand Rapids and Des Moines, both with increases of 32 percent (about 23 cents an hour for each city), were leaders in this respect. Average increases in the pie and pastry branch ranged from 4.8 percent (3 cents) in York to 34.1 percent (16 cents) in Duluth. The highest increase during the study year in the Hebrew baking branch was recorded by Providence (29 percent, about 31 cents), while San Francisco led the other national baking branch with a like percentage increase (amounting to 31.5 cents). Scranton reported the most significant increase in the cracker and cooky branch (26 percent or 13 cents).

---

[4] These percentage changes were based on specific rates weighted by the number of members workng at each rate. Only those quotations showing comparable data for both 1945 and 1946 were included. Specific increases during the 12-month period of this study reflect larger percentage changes among those lassifications with comparatively lower scales. Thus, if cracker and cooky bakers in city A increased heir rate 10 cents an hour from 50 to 60 cents, an average increase of 20 percent was registered, while of the same absolute increase raised the rate for cracker bakers in city B from 90 cents to $1.00 an hour, he percentage change was only 11.1 percent.

[1] Data not available.

[2] Includes Rock Island and Moline Ill. and Davenport, Iowa.

Average Wage Rates by Size of City and Region

City size is a significant factor in wage rate levels in the baking industry. The average of hourly rates of cities having over 1 million population was 12 cents higher than that recorded for cities of 500,000 to 1 million, while a differential of 10 cents favored the latter group over cities with 250,000 to 500,000 population. Comparison of cities of 100,000 to 250,000 and cities of 40,000 to 100,000 with those in the next highest population group, revealed average differences of 3 cents an hour favoring the larger cities.

In 7 of 8 possible comparisons, the North and Pacific region had averages ranging higher by as much as 33 cents, than the South and Southwest regions. The 33-cent difference was recorded for group III bread and cake hand shops favoring the North and Pacific over the South and Southwest group.

TABLE 5.—*Average hourly wage rates in cities of specified population groups* [1]

Type of baking	Group I [2]	Group II [2]	Group III			Group IV			Group V		
	North and Pacific	North and Pacific	All cities	North and Pacific	South and Southwest	All cities	North and Pacific	South and Southwest	All cities	North and Pacific	South and Southwest

[2] No city of this size in the South or Southwest.

[3] French, Polish, Bohemian, Scandinavian, Spanish, Italian, etc.

Straight-Time Weekly Hours [5]

The average straight-time workweek of the organized bakery workers covered in the 70 reporting cities was 41 hours (table 6). Bread and cake machine-shop and cracker and cooky workers had the shortest average hours (40 per week), while those in Hebrew products baking had the longest (45.8).

Almost 8 of every 10 members tabulated, worked under agreements providing for a workweek of 40 straight-time hours. A majority of the remaining members were limited to straight-time workweeks of 48 hours. The shortest workweek reported, 35 hours, was applicable to workers in Bohemian hand shops in New York City, while the longest, 54 hours, applied to shipping clerks in a Tampa, Fla., machine baking shop.

Straight-time hour reductions since July 1, 1945 affected 4 percent of the members tabulated, mainly in hand shops and other national baking. A few quotations, affecting but 2 percent of the workers in the latter branch indicated increased hours. In at least two cities reductions of as much as 8 hours per week were recorded.

TABLE 6.—*Distribution of union members in the bakery trades, by straight-time hours per week, July 1, 1946*

Weekly hours	Percent of union members with specified hours per week—						
	All types	Bread and cake, hand	Bread and cake, machine	Pie and pastry	Hebrew baking	Other national baking [1]	Crackers and cookies
Under 40	2.1	....	3.4	....	....	7.7	....

Average weekly hours	41.1	45.1	40.0	40.3	45.8	43.1	40.0

[1] French, Polish, Bohemian, Spanish, Italian, etc.

[2] Less than .05 of 1 percent.

With few exceptions, virtually all of the workers in cracker and cooky shops, pie and pastry and bread and cake machine shops, as well as almost half of those engaged in other national baking, had a regular workweek of 40 hours. Over 40 percent of the latter branch, 55 percent of the bread and cake hand members and 49 percent of those employed in Hebrew baking worked 48 straight-time hours. At least a third of those in the Hebrew products branch had a workweek of 45 hours.

---

[5] Weekly hours considered here refer to the maximum number of hours per week permitted by union agreements before overtime rates become effective. The actual number of hours worked in any 1 week may be greater or less than the weekly hours discussed.

Overtime and Sunday Rates

Ninety-eight percent of the workers tabulated were covered by overtime provisions stipulating payment of time and a half for weekly overtime operations (table 7). Most of the remaining members worked under agreements not specifying any definite rate for work performed beyond the contract hours.

Double time for work performed on the seventh consecutive day or Sunday, if an unscheduled work day, covered over 36 percent of the tradesmen studied; a slightly smaller proportion (33.6 percent) received time and a half for such assignments. Almost 3 of every 10 workers, encompassing substantial portions of Hebrew bakers (51 percent), pie and pastry workers (49 percent) and bread and cake hand shopmen (42 percent) worked under agreements in which no Sunday rate was specified. Agreements prohibiting Sunday work affected but a minute proportion (0.8 percent) of the members.

TABLE 7.—*Overtime rates provided in union bakery agreements, July 1, 1946*

Provisions	All types	Bread and cake, hand	Bread and cake, machine	Pie and pastry	Hebrew baking	Other national baking [1]	Crackers and cookies

[1] French, Polish, Bohemian, Scandivian, Spanish, Italian, etc.
[2] Less than .05 of 1 percent.

Vacations

Practically all of the organized workers in the baking industry were covered by agreements providing for paid vacations. Better than 9 of every 10 members received at least 1 week after 1 year's service (table 8). Slightly under one-quarter of the tradesmen received 1 week after 1 year and 2 weeks after 3 years of service.

Among the individual trades, large proportions of the Hebrew bakers, bread and cake hand shopmen and those in specialized baking had vacation clauses providing for 2 weeks after 1 year. Slightly fewer than one-quarter of the pie and pastry workers had vacations of 1 week after 1 year and 2 weeks after 2 years, while better than a third of the remaining members had to serve an additional year to receive a second week. Almost two-thirds of those in the cracker and cooky branch and one-quarter of the bread and cake machine bakers were covered by contract clauses providing 1 week after 1 year and 2 weeks after 5 years.

About 9 percent of the members, mainly those in specialized shops, bread and cake hand and pie and pastry establishments worked under agreements providing other than standard vacation clauses.

Union Scales of Wages and Hours, by City

Table 9 lists the union hourly wage scales and the hours per week in effect July 1, 1945 and July 1, 1946 for bakery trades workers (by type of baking and occupation) in each of the cities wherein data were obtained. Where more than one union rate is in effect for the same occupation in the same city all are listed, with the letters A, B, C, etc. indicating the various contracts. The letter designation is not intended to imply relative importance of the agreements. Daily or weekly scales have been converted to hourly units to render the data comparable and facilitate measurement.

TABLE 9.—*Union scales of wages and hours in the bakery trades in selected cities, July 1, 1946 and July 1, 1945*

City and classification	July 1, 1946 Rate per hour	July 1, 1946 Hours per week	July 1, 1945 Rate per hour	July 1, 1945 Hours per week

UNITED STATES DEPARTMENT OF LABOR
L. B. Schwellenbach, *Secretary*

BUREAU OF LABOR STATISTICS
Ewan Clague, *Commissioner*

★

CONSTRUCTION IN THE WAR YEARS 1942–45

Employment, Expenditures, and Building Volume

Bulletin No. 915

For sale by the Superintendent of Documents, U. S. Government Printing Office
Washington 25, D. C. - Price 55 cents

Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., June 16, 1948.

The Secretary of Labor:

I have the honor to transmit herewith a statistical report showing trends in construction activity, particularly during the 4 years of World War II. In addition to presenting the effects of war on the construction industry, this report resumes the annual publication of a statistical bulletin on construction expenditures, employment, and building volume, interrupted in 1944 by wartime pressures.

This bulletin was prepared in the Bureau's Division of Construction Statistics, H. E. Riley, Chief. Henry F. Haase was in charge of statistical estimating and developed the tabulating and estimating techniques. Adela L. Stucke planned the tables and prepared the text, under the general direction of Dorothy K. Newman.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

Contents

Page
- Total construction activity 1
  - Expenditures for construction 1
    - Estimating construction expenditures 2
    - New construction expenditures, 1942–45 4
  - Employment in the construction industry 7
    - Estimating methods 7
    - Employment by type of project, 1941–45 8
    - Construction compared with total nonagricultural employment 9
  - Volume of Federal construction, 1935–45 10
    - Trend, 1935–45 11
    - Types of projects included in the program 12
- Building construction 12
  - Trends in city building 12
    - 257 cities, 1921–45 12
    - All urban areas, 1942–45 16
  - New housing units in nonfarm areas 22
    - Estimating dwellings started 22
    - Trends from 1910 through 1945 24
    - Monthly variations; influencing legislation and regulations, 1939–45 26
- Trends in private building construction costs 30
  - Composite index 31
  - Residential construction costs 35
- Shifts in location of construction activity in wartime 37
  - Flow between large and small places 37
    - Urban-rural movements 37
    - Size of city shifts 39
  - Geographic shifts 39
    - Between States 39
    - From region to region 47
- Appendix.—Building construction in all reporting cities, 1943, 1944, and 1945 57

Tables

1.—Estimated construction expenditures, by type of construction, 1915–45 2
2.—Estimated construction employment, private and public projects, 1929–45 7
3.—Estimated construction employment, by type of construction, 1941–45 8
4.—Estimated construction employment compared with nonagricultural employment, 1929–45 10
5.—Value of contracts awarded and force-account work started on construction projects financed wholly or partially from Federal funds, by type of project, 1935–45 11
6.—Estimated valuation, and indexes, of building construction for which permits were issued in 257 cities, by class of construction, 1921–45 13
7.—Estimated number of new family dwelling units for which permits were issued, in relation to population, in 257 cities, and index of residential rents, 1910–45 13
8.—Five cities leading in permit valuations for building construction, 1921–45 14
9.—Estimated number of new family dwelling units for which permits were issued in 257 cities, by type of structure, 1921–45 16
10.—Estimated valuation of the various classes of building construction for which permits were issued in all urban areas, by source of funds and by months, 1942–45 18
11.—Estimated valuation and number of new nonresidential buildings for which permits were issued in all urban areas, by type of building and by source of funds, 1942–45 19
12.—Indexes of the estimated number of new family dwelling units and valuation of the various classes of building construction for which permits were issued in urban areas, 1929–45 20
13.—Estimated number of new family dwelling units started in nonfarm areas, by type of area and by type of structure, 1910–45 24
14.—Estimated number and construction cost of new family dwelling units started in nonfarm areas, by source of funds, 1920–45 26

Page

15.—Estimated number of new family dwelling units started in nonfarm areas, by source of funds and by month, 1939–45 27
16.—Estimated number of new family dwelling units started in nonfarm areas, by source of funds and by quarter, 1935–45 29
17.—Indexes of construction costs and expenditures for new private building, 1934–45 31
18.—Average hourly and weekly earnings and weekly hours worked on private building construction, and index numbers, 1934–45 31
19.—Average hourly and weekly earnings and weekly hours worked on private building construction, by selected types of work, specified months, 1940–45 32
20.—Average hourly and weekly earnings and weekly hours worked on Federal construction projects, and index numbers, by type of project, 1935–45 33
21.—Average union hourly wage rates in selected building trades, 1934–45 34
22.—Union wage scales for selected building trades in 75 cities, June 1, 1940, July 1, 1942, and July 1, 1945 34
23.—Weighted indexes of wholesale prices of building materials, 1934–45 36
24.—Change in estimated construction cost of new private 1-family nonfarm dwellings, quarterly, 1940–45 36
25.—Estimated permit valuation per new family dwelling unit in 257 cities, by type of structure, 1921–45 37
26.—Estimated number and valuation of new family dwelling units for which permits were issued in nonfarm areas, by type of area, size of city, and source of funds, 1942–45 38
27.—Estimated number and valuation of privately financed new family dwelling units for which permits were issued in nonfarm areas, by type of area, size of city, and type of structure, 1942–45 38
28.—Estimated valuation of the various classes of building construction for which permits were issued in all urban areas, by size of city and by source of funds, 1942–45 40
29.—Estimated number of new family dwelling units for which permits were issued in nonfarm areas, by geographic division, by State, and by source of funds, 1940–45 42
30.—Estimated number and valuation of privately financed new family dwelling units for which permits were issued in nonfarm areas, by State and by type of structure, 1940–45 43

CONSTRUCTION IN THE WAR YEARS

Total Construction Activity

Expenditures for Construction

The course of construction activity during the years 1940 to 1945 reflects clearly the pressures and tensions of a wartime economy. Stimulated first by the national defense program and later by the all-out war production effort, expenditures for construction reached a new high in 1942—over 14 billion dollars. By 1944, however, as a result of the completion of most war construction and curtailment of all nonessential building, expenditures had dropped to less than 5 billion dollars—a 66-percent decline. This was the most violent downsweep in any 2-year period for which reliable figures are available. Thus, the developing construction boom of the 1940's was split in two by the war.

Available evidence, dating from 1915, points to a similarity in the pattern of both long-term trends in construction expenditures and general movements in the value of gross national product.[1] Major swings occur in both series at about the same time, but fluctuations are more extreme in the case of construction. During the period between World Wars I and II, for example, construction volume and national product both were at peak in the last half of the 1920's and both dropped to the low point in their cycle in the depression year of 1933. The range from peak to trough for construction expenditures was 79 percent (from 12.3 billion to 2.6 billion dollars), in contrast to 45 percent (from 99.4 billion to 54.8 billion dollars) for national product.

From 1934 on, construction activity moved in the same direction with general business activity but expanded more rapidly, until 1942. Then the

---

[1] Gross national product figures shown here are derived by the U. S. Department of Commerce. Estimates for the period prior to 1929 are adjusted data of the National Bureau of Economic Research.

impact of the war caused the two series to develop opposite trends—business continued sharply upward while construction was forced to contract drastically. As soon as the war ended, however, construction began to expand at a much higher rate than national product as a whole.

Although these figures, which are in current dollars, may not state the case fully because they do not allow for changes in prices and differences in pricing bases between war and nonwar production, they demonstrate adequately the relationship of movements in the construction industry to those in the economy as a whole. The extreme year-to-year fluctuations which characterize construction activity cause repercussions upon other components of general business. For this reason, and because it is the largest single industry except agriculture, construction is a particularly important part of the economy.

Estimating construction expenditures

Construction expenditures are a measure of the dollar value of construction work actually done. Hence, they differ from the building permit and contract award series, discussed on pages 12–22, which represents the value of work planned to be started immediately or in the near future. Expenditures include the installed value of equipment considered

---

[1] Revised as of April 1947.

[2] Estimates of new construction from 1915 through 1938, except for nonfarm residential building, were made by the Office of Domestic Commerce, U. S. Department of Commerce. For 1939 and subsequent years estimates were made jointly by the Bureau of Labor Statistics, U. S. Department of Labor, and the Office of Domestic Commerce. New construction includes expenditures for major additions and alterations.

[3] Excludes nonresidential building by privately owned public utilities.

[4] Unavailable.

[5] Public industrial and commercial building not segregable from private for 1920 through 1932, but the amount involved is believed to be negligible.

[6] Included in "State."

[7] Excludes residential nonfarm minor building repairs because the data are unavailable.

[8] Covers privately financed structural repairs of the type for which building permits are generally required.

[9] Covers maintenance and repairs.

an integral part of a structure, but exclude the value of land, machinery, and movable equipment. Included under new construction is the value of major additions and alterations. Minor building repairs, which are shown separately, include those types of work for which building permits are generally issued. They exclude maintenance work such as painting, plumbing and heating, waterproofing, papering, electrical repairs, etc., not incident to structural repairs.

Estimates of expenditures for private residential building are based on the valuation figures recorded on reports of building permits issued, which are submitted to the Bureau of Labor Statistics by local building officials. These data are adjusted to account for residential building activity in nonpermit issuing places, abandonments, and for the understatement of construction costs inherent in building permit valuations.

Separate estimates are made for each of several types of private nonresidential building, based upon records of contracts awarded as reported monthly by the F. W. Dodge Corp. Estimates for the other types of construction, Federal and non-Federal, are for the most part derived from reports obtained from other government agencies and private industry, as well as published sources such as the weekly periodical, Engineering News-Record, and the annuals, Budget of the United States Government and Financial Statistics of Cities.

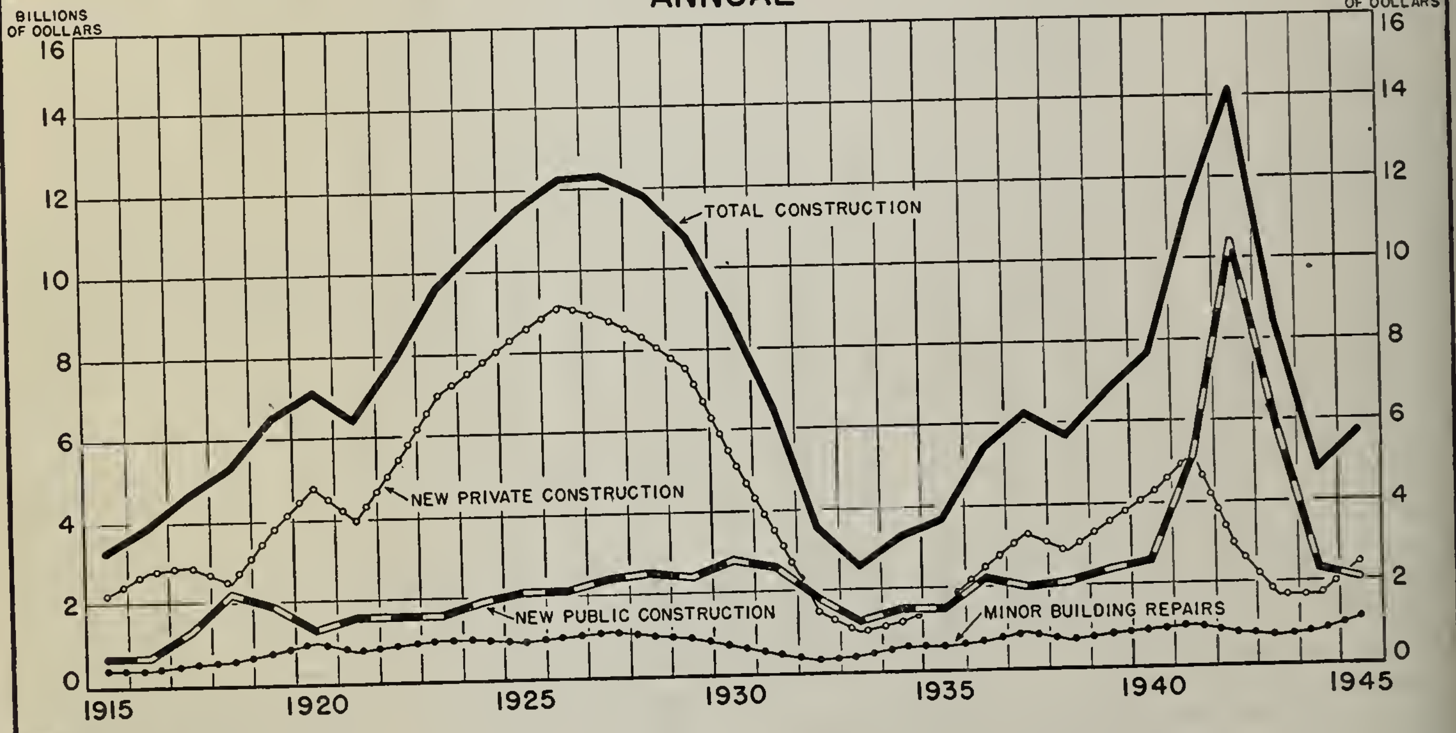
New construction expenditures, 1942–45

New private construction expenditures, which accounted for approximately 80 percent of all the money spent for new construction during the entire period of the 1920's, dropped to 22 percent of the total in 1942, the first year of World War II. In 1942, outlays from private funds amounted to only 2.9 billion dollars, compared with the 1926 peak of over 9 billion dollars. On the other hand, an unprecedented volume of publicly financed construction (10.4 billion dollars) brought the total for new work to 13.3 billion dollars—the highest level in the country's history.

CHART 2

CONSTRUCTION EXPENDITURES

ANNUAL



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

Expenditures for military and naval facilities construction, which ordinarily account for only a few million, and even in 1918 totaled but 1.6 billion dollars, rose to over 5 billion dollars in 1942. This was almost two-fifths of the 1942 expenditures for all new work. The largest category after military and naval facilities was publicly financed industrial buildings, which reached the unprecedented amount of 3.4 billion dollars. In no year prior to 1941 was more than about 164 million dollars spent for construction of new public industrial buildings. Highway construction, which normally forms a larger part of the public total than any of the other classes, exceeded a billion dollars each year between 1925 and 1931 but fell to 675 million dollars in 1942.

Private residential construction, at 1.3 billion dollars, comprised the third largest segment of new construction expenditures in the opening war year. This was less than half the amount (2.8 billion dollars) spent in the good prewar home-building year 1941.

In 1943, new construction expenditures totaled 7.7 billion dollars—a drop of more than 40 percent from the 1942 high mark; in 1944, they fell even more—to around 4 billion dollars. Completion of most war construction projects was entirely responsible for the drop between 1943 and 1944. Private work was about the same in both years, 1.7 billion dollars, whereas public activity declined from 6 billion dollars in 1943 to 2.3 billion dollars in 1944.

By 1944, construction of military and naval facilities was down to 837 million dollars; private residential building accounted for only 535 million dollars, and publicly financed industrial buildings for 507 million dollars.

Commercial building financed from private funds shrank to 32 million dollars in 1943—the lowest dollar volume in any year for which estimates are available. In the middle 1920's this type of construction came to over a billion dollars a year.

Privately financed construction, previously restricted by wartime necessities, was allowed to expand prior to the actual termination of the war. Limitation orders were eased at an early date, opening the road to recovery of civilian construction. The problems connected with reconversion were not the same in the construction industry as those confronting manufacturers. For example, there were no plants to clear out, very little war work to complete, and few contracts to terminate. On the other hand, a great deal of recruitment was necessary to expand the construction work force. In addition, there was the task of organizing new undertakings, getting materials assembled on the site, and obtaining sufficient supplies of building materials from plants operating far below capacity.

Work forged ahead on many fronts, however, as soon as labor was recruited and the required inventories were accumulated. The latter, especially, presented grave obstacles, but they were overcome sufficiently for construction to advance notably in the closing months of 1945. The dollar volume of new private construction put in place in the last half of the year was about double that for the first 6 months.

For the year as a whole, new construction expenditures totaled 4.6 billion dollars, an increase of 13 percent over 1944. One of the outstanding features of this expansion was the marked shift in importance between publicly and privately financed activity. In the early part of 1945, expenditures averaged over 160 million dollars a month for new public construction and around 120 million dollars for new private work. By December, the public construction volume dropped to 98 million dollars, but private activity rose to 352 million dollars.

The greatest advance, by far, took place in private nonresidential building construction. This was one of the first areas to be affected by the changing military situation. On May 29, 1945, and again on June 11, the War Production Board relaxed the terms of L–41[2] to hasten the construction or alteration of industrial plants for the production of bottleneck items and essential civilian articles in short supply. These amendments were made to insure that limitations on construction would not obstruct the rapid reconversion of industry nor delay the reemployment in civilian production of the greatest possible number of workers.

This policy was further implemented as soon as the war was over by the issuance of an order permitting the building of industrial plants without WPB authorization after August 21, 1945. Consequently, outlays for new private nonresidential building construction in 1945 amounted to over a billion dollars, three-fifths of which were for industrial facilities. The 1944 figure for private nonresidential building (350 million dollars) was about a third of the 1945 total.

Private new residential construction also increased substantially in 1945. All during the war, home building had been subordinated to the needs of vital industrial construction, so that the demand for new houses was extremely urgent by the end of the period. On the assumption that the most expeditious way to get an immediate expansion of residential building was to remove restrictions on all construction, the War Production Board revoked L–41 on October 15, 1945. As a result expenditure figures for the last months of 1945 rose markedly. Within the short span of a year the monthly volume of private housing expenditures increased fivefold. In the first quarter of 1945 the monthly rate was about 23 million dollars, the lowest in the entire war period; by December, despite normal seasonal tendencies, it was 116 million dollars. During the entire year, 670 million dollars was spent for residential building—a fourth above the 1944 dollar volume.

---

[2] Conservation Order L–41 was issued on April 9, 1942, placing all construction under rigid control. The order made it necessary for builders to obtain authorization from the War Production Board to begin residential construction costing $500 or more; agricultural construction costing $1,000 or more; or commercial and other construction costing $5,000 or more during any continuous 12-month period.

[1] Covers all types of workers (wage earners, salaried employees, working proprietors, and self-employed persons, as well as force-account workers) actively engaged on all types of new construction work and on alteration, addition, and repair work of the kind usually covered by building permits. (Force-account employees are workers hired, not through a contractor, but directly by a business or government agency, and utilized as a separate work force to perform nonmaintenance construction work on the agency's own properties.) Persons engaged in maintenance work are not included.

These estimates indicate average employment during the month (as distinguished from the number of different persons shown on pay-roll or employment records) and have been derived primarily by the conversion of dollar-expenditure figures into employment by the use of average performance factors.

Employment in the Construction Industry

Estimating methods

Construction employment figures presented in this section are estimates of the average number of workers employed in connection with construction operations in the United States. They include wage earners and salaried employees engaged on all types of new construction work and on alteration, addition, and repair work of the kind usually covered by building permits. Force-account workers[3] are also included, as well as self-employed persons, working proprietors, and workers employed by construction firms either on or off the construction site. The estimates exclude persons engaged in maintenance work.

The employment averages are derived primarily by converting construction expenditure figures into the average number of man-months of labor ordinarily required to perform the volume of work reported, using a currently adjusted figure for the value of work performed per man per month. The average employment figures obtained for the periods specified (man-months of employment) may be considerably lower than the number of different individuals employed during these periods as shown on pay-roll records, because of the high turn-over in the construction industry.

It should be noted that the above procedure is used only in the case of nonfederally financed construction. In the case of Federal construction, employment is estimated directly from reports on employment obtained from contractors.

Estimates of the value of work performed per man-month on non-Federal work are adjusted regularly for changes in average hourly earnings and in the average workweek of construction workers, as well as for changes in materials prices. They are checked periodically also against actual experience, using data on the operation of sample projects under construction.

---

[3] Force-account employees are workers hired not through a contractor, but directly by a business or government agency, and utilized as a separate work force to perform nonmaintenance construction work on the agency's own properties.

It is assumed in making these adjustments that contractors' overhead and profit remain a constant percentage of the value of work performed. This assumption introduces error in the results, since the percentage undoubtedly changes with competitive conditions and as mechanization and other developments in method of operation affect overhead. Another assumption affecting the level of the employment figures is that productivity per man-hour is constant. While changes in productivity are ordinarily slow, they can be rapid when technological developments occur. They are both rapid and erratic during periods of shortages and other conditions of disorganization similar to those of the recent past. Sufficient information is not available to adjust for these considerations. The average employment figures shown must therefore be interpreted accordingly.

Employment by type of project, 1941–45

During 1941 and 1942, employment on all types of construction projects exceeded the 2-million-mark for the first time in a decade. Average monthly employment on public construction projects, which had fluctuated relatively little during the 12 years 1929–40, rose almost constantly during early war preparations to an unprecedented level of 1,950,000 persons in August 1942. The decline from that month on was consistent and rapid. In fact, the decrease in 1943 released an average of almost 86,000 persons a month. (More than 90 percent of the publicly financed war construction program was completed by the end of 1943.) Average employment on public construction for 1943 was 957,000, compared with 1,488,000 in 1942, and by 1945, the average for the year was only 283,000.

With recovery and growing economic prosperity, average employment on private construction projects rose steeply in the early defense period, reaching almost 1,800,000 in July 1941. The high employment volume in 1929 (which averaged 2½ million for the year) was never again attained, however, for late in 1941 control of materials and restrictions on private projects were imposed to assure materials and men for war production. Private construction employment then decreased sharply to an average of 726,000 workers in 1942, slightly over half the 1,423,000 average for 1941. The decline to 375,000 in 1944 gave employment to 21 percent fewer workers in that year than in the depression year 1933. Although the monthly average for the entire year had recovered to only 685,000 in 1945, by December over a million persons were working on private construction, foreshadowing the surge in postwar building.

TABLE 3.—*Estimated construction employment, by type of construction, 1941–45*[1]

[1] See footnote 1, table 2.

[2] Includes construction workers engaged on the atomic bomb project.

[3] Mainly airports, water and sewer systems, and electrification projects.

[4] Includes community buildings, water supply and sewage disposal projects, and miscellaneous public service enterprises.

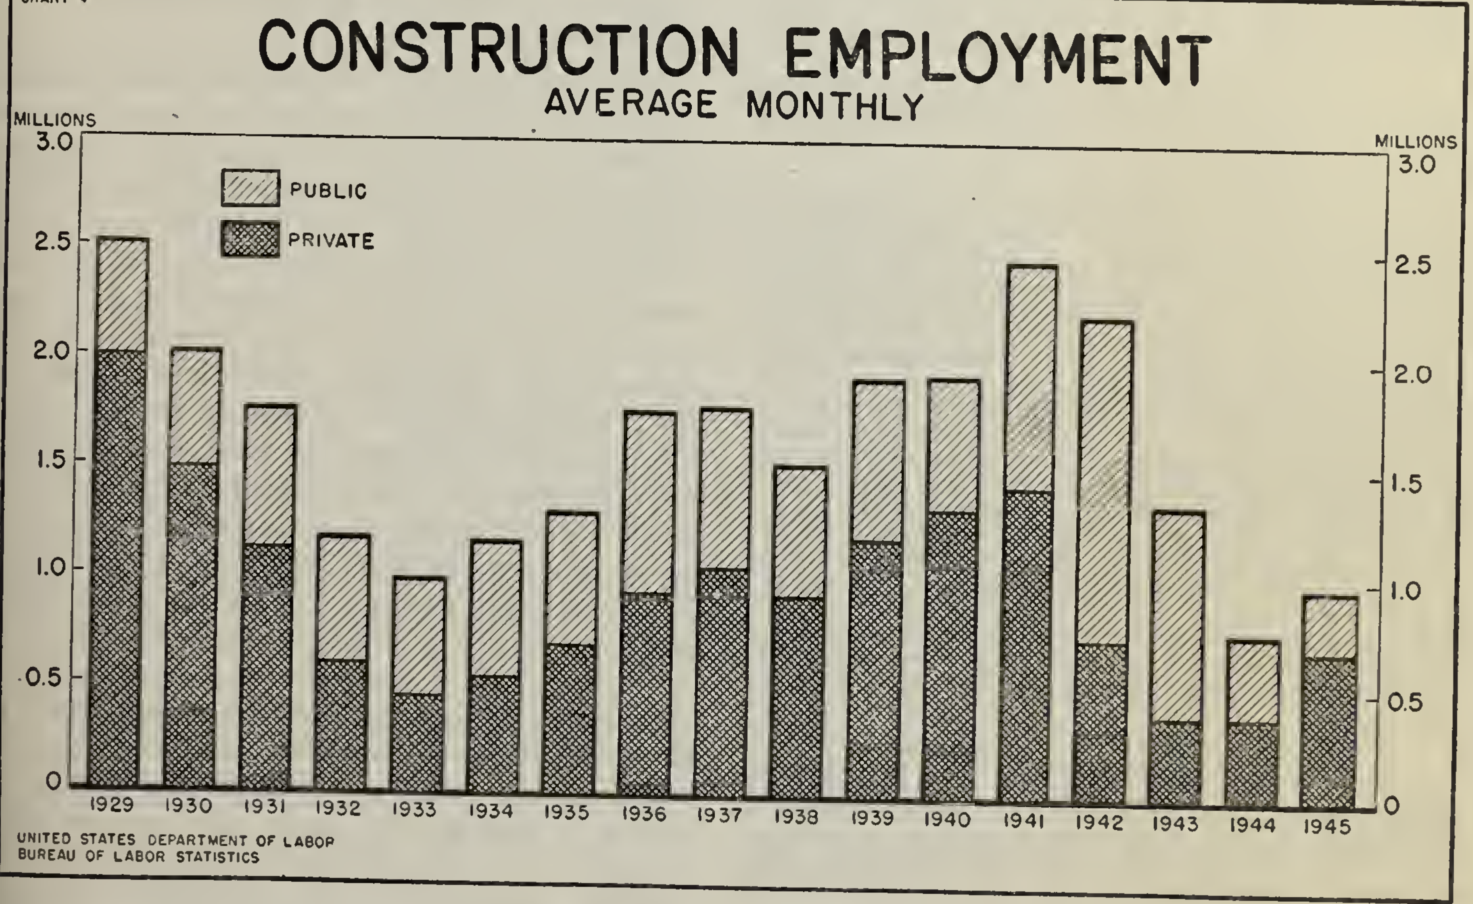
About half the 2 million persons engaged on new construction in 1942 were working on federally financed nonresidential building projects such as barracks, ordnance plants, shipbuilding and repair facilities, and warehouses. This type of employment, which declined over 40 percent between 1942 and 1943 and another 63 percent in the following year, dropped to a monthly average of 157,000 in 1945.

Because of the need for emergency housing and highways to move war goods, Federal residential building and non-Federal street and highway construction were the next most important types of public projects in providing employment in the defense and early war periods. About 85,000 workers were employed on the former and 115,000 on the latter in 1941. By 1945, however, the respective averages were 11,000 and 28,000.

Home construction has been the most important segment of private building, and in 1941, the very good housing year, 627,000 workers were employed on privately financed residential building. A rapid decline to an average of 256,000 in 1942 was brought about by the initiation of construction controls in April of that year. In 1944, the monthly employment figure for new private residential construction averaged only 88,000; but it increased by almost 50 percent in 1945.

Both residential and nonresidential building were given impetus by the lifting of wartime controls in 1945; however, the backlog of ready funds and completed plans was especially great in business and industry. Although privately financed nonresidential building accounted for only about half as much employment as residential building in 1941, the relationship was reversed as soon as the war ended. In 1945 an average of 200,000 persons a month were working on private new nonresidential building, compared with 129,000 on new housing construction.

CHART 4



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

Construction compared with total nonagricultural employment

An approximation of the weight of construction in the whole nonagricultural employment picture is given in table 4. It should be noted that figures shown for employment in all nonagricultural establishments exclude the self-employed, working proprietors, and firm members, whereas estimates for construction employment include such persons.

In addition, the construction employment series is designed to show the total employment effect of construction activity and, therefore, includes employees of nonconstruction (or multi-industry) organizations who may engage in construction. For example, a firm concerned principally with the marketing of lumber may at the same time contract for and build houses. Workers of such a firm would be counted in the nonagricultural series under wholesale or retail trade and again in the construction series under residential building.

Recognizing that the two series are not directly comparable because of the inclusion of self-employed and firm members in construction estimates, the series do, nevertheless, provide a rough measure of the relative importance of all construction employment to total nonagricultural employment.

Construction employment appears from such a comparison to be an exaggerated indicator of the trend in all nonfarm work, because it comprises a much greater proportion of total nonagricultural

TABLE 4.—*Estimated construction employment compared with nonagricultural employment, 1929–45*[1]

[1] Data on employment in all nonagricultural establishments cover wage and salaried employees and exclude self-employed persons, working proprietors, and firm members. All of the groups mentioned are included in the construction employment estimates. The wage earners and salaried employees included in the construction series are construction and special trades contractors' wage-earner and salaried employees, whether working at the construction site or in the contractors' offices, shops, or yards.

The construction employment estimates are designed to show all employment afforded by construction activity; thus, they cover all persons performing work on, or employed on work directly incident to, new construction, major additions and alterations, and building repairs of the type for which building permits are usually issued. These employees are included even if working as force-account workers or as contract-construction employees in industries classified as nonconstruction for the purposes of the nonagricultural series. Persons engaged in maintenance work, however, are not included.

Force-account employees are workers hired, not through a contractor, but directly by a business or government agency, and utilized as a separate work force to perform nonmaintenance construction work on the agency's own properties.

employment in prosperous peacetime years than in depression years. Construction activity is affected so directly by good or bad times that employment in this field increases or falls off proportionately more than in industry as a whole.

Employment on construction projects comprised over 8 percent of the estimated total (31.1 million workers) employed in all nonagricultural establishments in 1929. After this boom year, the proportion of construction employment to total nonagricultural employment dropped each year to an average of 4.5 percent in the depression years 1933–35. Construction employment rose again in importance in the total nonagricultural labor force beginning with 1936; between 1936 and 1940 construction site workers comprised about 6 percent of all nonagricultural workers, and in 1941 the proportion was 6.9 percent.

Total industrial employment continued to rise steeply during the war years, while restraints on nonessential construction activity, instituted in 1942, and subsequent completion of the major part of the war construction program caused employment in the construction industry to fall off heavily. In 1943 construction employment comprised only 3.3 percent of the nonagricultural employed labor force, and in 1944 as little as 1.9 percent. By 1945, construction rose to 2.5 percent of total nonagricultural employment, but that was still below the proportion for the depression year 1933.

Volume of Federal Construction, 1935–45

A good indicator of the fluctuations in Federal construction in response to national programs and policies, is the value of contracts awarded and force-account work started on construction projects financed from Federal funds (either wholly or partially). Construction work by force account under a Federal agency is work for which no contract is let but which is conducted directly by the agency itself. The workers are usually employed for a specific project at completion of which their services may be terminated. Data presented here are a compilation of reports from Federal agencies on the value of construction contracts they awarded or of force-account work they started. Estimates of actual expenditures on all public works, State and local as well as Federal, are given on pages 2 to 6.

During the 11-year period January 1935 to December 1945, Federal construction awards and force-account work came to almost 29 billion dollars.[4] Considerably more than half of that amount, or 16 billion dollars, was for nonresidential building construction; the remainder, over 12 billion dollars, was spent for such construction projects as highways and roads, housing, airports, bridges, reclamation, and water supply and sewerage systems. In addition to projects financed from regular Federal appropriations, four emergency or special construction programs were either in operation or introduced within the 11-year period covered. The first and largest of these was the Public Works Administration program, which began in July 1933 and was practically completed by December 1941. The next largest program, financed from Work Projects Administration funds, but operated by other Federal agencies, included projects other than work relief and was in effect during the period July 1935 to December 1941. The other two programs were the low-rent housing projects under the United States Housing Authority, and the construction of schools, water systems, sewer systems, and various other types of facilities needed in crowded war areas under the War Public Works program begun in late 1941.

---

[4] Data presented here somewhat understate the final value of contrac awards, since it was impractical to ascertain every revision made in initia construction estimates, and projects classified as secret by the militar (including atomic bomb production facilities) are excluded.

Trend, 1935–45

Although there has always been some construction financed by regular Federal appropriations, the PWA program in 1933 was the forerunner of large-scale Federal public works programs. From 1935 to 1939 well over three-fifths of Federal construction award values were for PWA and WPA projects. After extension of PWA from funds made available by the Emergency Relief Appropriation Act of 1935 and the inception of the WPA program financed from the same act, the contracts awarded or force-account work started in 1935 amounted to somewhat over 1¼ billion dollars—87 percent of the total for the year. Continuance of the PWA and WPA programs in 1936 raised the value of Federal awards slightly—from 1,478 million to 1,543 million dollars. Smaller PWA appropriations and a reduction in amounts transferred from WPA funds to Federal construction work in 1937 resulted in a drop in total Federal awards of nearly half a billion dollars. The 1937 figure of 1,046 million dollars was the lowest for any year, except 1945, during the 11-year period. Passage of the Public Works Administration Act of 1938 and the inception of the USHA program, however, caused total awards to mount again in 1938 and remain steady in 1939.

The next few years witnessed the introduction of the "defense program," in June 1940 and the "war program," after the attack on Pearl Harbor. PWA and WPA were decreasing in importance, but the defense program, including the first cantonment camp project, pushed 1940 Federal construction awards to $2,395,000,000, well over two-fifths above the 1939 figure. With increased demands for military camps and posts, and expanded construction of such production facilities as shipyards and aircraft and other munitions plants, the total for 1941 rose abruptly to $6,014,000,000, over 2½ times that for the previous year. The peak was reached in 1942 when contract awards for the war construction program amounted to more than $7,814,000,000, or 27 percent of the total for the entire period 1935–45.

A sudden drop occurred the following year, however, to a figure near the 1940 level because many of the most important war construction projects were already under way. Thus, in the 4-year period 1940–43, nearly 19 billion dollars worth of contracts were awarded for defense and war purposes, amounting to 66 percent of the 11-year total and over 2½ times the total for the 5 years 1935–39.

TABLE 5.—*Value of contracts awarded and force-account work started on construction financed wholly or partially from Federal funds, by type of project, 1935–45*[1]

Type of project	Value (in thousands of dollars)

[1] Data somewhat understate the final value of contract awards, since it was impractical to ascertain every revision made in initial construction estimates, and projects classified as secret by the military (including atomic bomb production facilities) are excluded. Figures for 1935 through 1942 include off-continent construction.

[2] Excludes hangars and other buildings, which are included under building construction.

[3] Includes additions, alterations, and repairs.

[4] Covers primarily loans granted by the Rural Electrification Administration. Includes hydroelectric power plants.

[5] Covers forestry, railroad construction, and other types of heavy engineering projects, and various military installations, n.e.c.

[6] Included in "All other types".

[7] Includes nonresidential construction at the site of 3 Resettlement Administration projects for which a breakdown of residential and nonresidential costs is not available.

Further reductions occurred in 1944 as the bulk of the war construction projects were completed; and in 1945 the total dropped to $1,030,000,000, the lowest volume reported in any year in the period under discussion.

Types of projects included in the program

Of all the types of projects undertaken, nonresidential building construction was by far the most important. The money for nonresidential building (16 billion dollars), from 1935 to 1945, was allocated for schools, hospitals, post offices, public buildings of all types, and, in connection with the war program, cantonment camps and barracks; hangars, magazines and storehouses, and the many different types of industrial plants and factories required to produce the supplies and equipment needed by a Nation at war. Next in importance in amount of contract awards was street, road, and highway construction with about 3½ billion dollars. Over four-fifths of this amount was administered under the Public Roads Administration.

Slum-clearance and low-rent housing projects accounted for nearly 2 billion dollars in awards and were built largely under jurisdiction of three agencies: The Housing Division of PWA, the United States Housing Authority, and the Federal Public Housing Authority, the latter having major responsibility for the large war housing program. Airport construction (with awards of $1,616,000,000), river, harbor, and flood-control projects ($1,204,000,000), and reclamation projects ($1,042,000,000) were the only other types to reach the billion-dollar mark.

The reclamation work that was carried on under Federal contract included large dams in the West and the TVA in the South. Enlargement and improvement of the Panama Canal, accounting for more than 275 million dollars appropriated in 1941, and construction of the Midtown Hudson Tunnel of New York City were among the largest heavy-engineering projects accomplished in the 11-year period. Miscellaneous projects swelled the total, especially in 1941 and 1942 when a great number of multiple-use military installations were begun. Sometimes as many as five or six different types of facilities were provided in one project—barracks, roads, sanitation, communication, and training facilities, hospitals, and administration buildings.

Building Construction

Building construction comprises the largest and most violently fluctuating part of total construction activity and strongly influences the behavior of the remainder. A great deal of nonbuilding construction, such as streets and highways, pipe lines, sewer systems, telephone equipment, which follows immediately after or is performed simultaneously with building construction, constitutes the other part of what is practically a joint demand. When building construction rises and falls, therefore, nonbuilding moves in the same direction, although frequently not to the same extreme degree.

During the 30-year period 1915–45, expenditures for building construction in almost every year amounted to at least half the dollar volume of all construction put in place, and in a number of years the proportion was well over three-fifths (table 1). In prosperous years especially, building construction forms the major part of the total.

Trends in City Building

257 cities, 1921–45

To relate current activity to past performances in city building construction, the Bureau of Labor Statistics prepares series showing the annual volume of building construction since 1921 in 257 large cities[5] (tables 6, 7, and 9). From 1929 on, building-construction trends are reflected more accurately through indexes (see table 12), which are based on data from a larger and more representative sample of incorporated places.

Both sets of figures reveal an almost continuous upward trend in permit valuation[6] of building con-

---

[5] Cities with population of 25,000 or more, of which there were 412 in 1940. The 257 cities are marked with an asterisk in the appendix—Building Construction Reported to the Bureau of Labor Statistics, by City and by Class of Construction, 1943, 1944, and 1945 (p. 57).

[6] Permit valuation figures are estimates based on reports of construction cost as recorded on building permits, and on notifications of Federal building construction contracts awarded.

[1] Includes number of units for which Federal construction contracts were awarded.

[2] Population figures are actual enumerations for the 257 cities in the census years 1910, 1920, 1930, and 1940; estimates for other years prior to 1940 are straight-line interpolations of Census figures while those subsequent to 1940 are based on the 1940 Census, since no further information is available.

[3] Estimates for the period prior to 1921 are based on building-permit data made available by the building-permit survey which the Bureau of Labor Statistics conducted in cooperation with the Work Projects Administration. Data were available for 118 cities for 1910 and for a progressively greater number of cities each successive year, reaching a total of 229 cities in 1926. Since that time, all 257 cities have reported directly to the Bureau.

[4] Bureau of Labor Statistics index of rents for wage earners and lower-salaried workers in large cities.

[5] Data not available.

TABLE 8.—*Five cities leading in permit valuation*[1] *for building construction, 1921–45*

Year and city	Permit valuation
1921: New York	$442,285,248
Chicago	133,027,910
Cleveland	86,680,023
Los Angeles	82,761,386
Detroit	58,086,053
1922: New York	645,176,481
Chicago	229,853,125
Los Angeles	121,206,787
Philadelphia	114,190,525
Detroit	93,614,593
1923: New York	789,265,335
Chicago	334,164,404

Houston	45,335,871
New York	35,090,013

[1] Includes value of Federal construction contracts awarded.

New York City data are not exactly comparable throughout the years. From 1921 through 1944 figures presented here are based on applications filed rather than on permits issued. For the years 1942 through 1944 large projects which were definitely determined to represent postwar plans have been omitted. Figures for 1945 are based on inspection records and represent work actually started.

· Data for Boston are based on permit applications filed rather than building permits issued.

struction, commencing immediately after the depression low in 1933 and lasting through 1941. This was followed by a sharp decline in 1942, further decreases in 1943 and 1944, and the first signs of recovery in 1945.

Permit valuations in the 257 cities in 1944 were less than half as great as in 1942, the first war year, but were almost double the figure for 1933 when building slumped to the lowest point recorded in the 2½ decades for which data are shown. Valuations were highest in the 1920's, especially 1925 and 1926. Only in 1941 when national-defense building was in its stride has any year since 1929 even approached the level of building construction between 1922 and 1929. Except for 1935, the 1944 figure was the lowest in a decade; however, in 1945 valuations rose again by 63 percent.

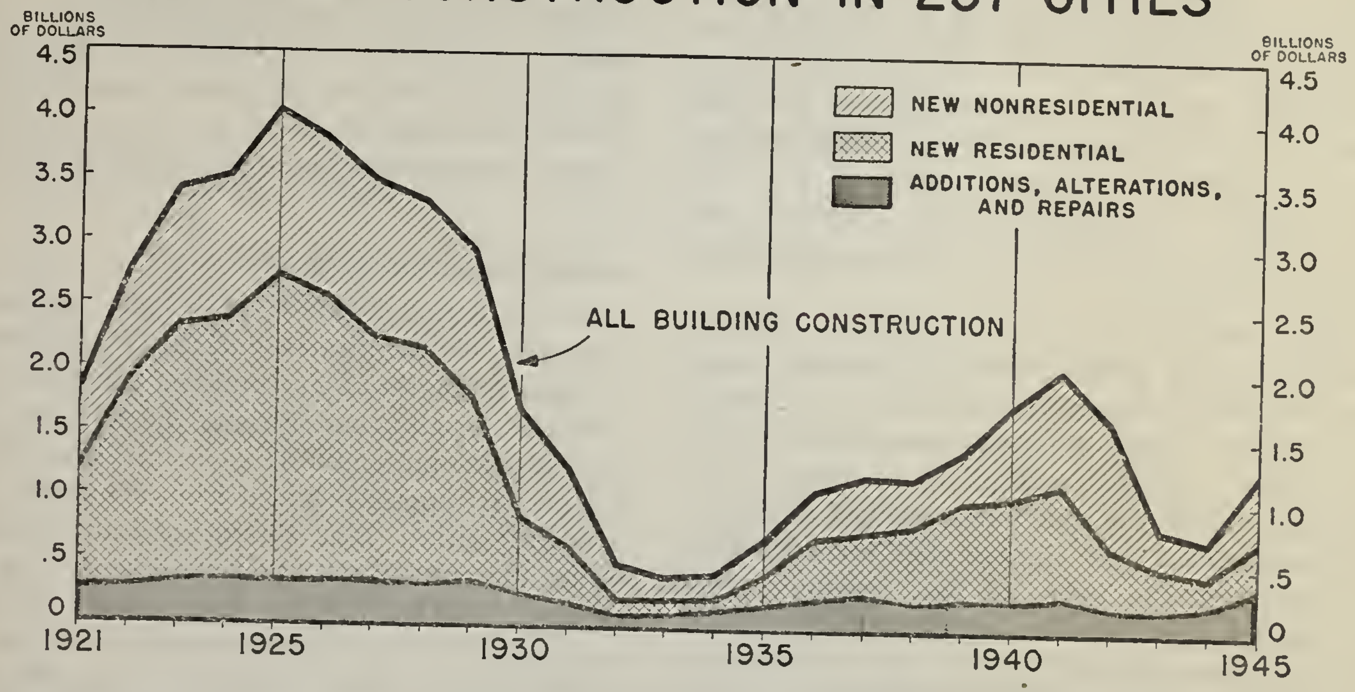
Usually residential building[7] exceeds nonresidential, and in prosperous years it accounts for the major part of building activity. In the depression years 1930–35, on the other hand, and in the defense and war years 1941 and 1942, the reverse was true. In fact, new residential building valuations fell so low in 1933 and 1934 that they were considerably below those reported for additions, alterations, and repairs. In 1942 permit valuations in the 257 cities for nonresidential building were more than twice the residential, mainly because of extensive construction of military and war industry facilities and rigid curtailment under Government order of nonessential building.

---

[7] Building permit data on residential construction include hotels, lodging houses, and such miscellaneous living quarters as dormitories and clubs, in addition to the housekeeping accommodations which are referred to as "new family dwelling units" in other parts of this section.

CHART 5

ESTIMATED PERMIT VALUATION OF BUILDING CONSTRUCTION IN 257 CITIES



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

INCLUDES VALUE OF BUILDING CONSTRUCTION IN THE 257 CITIES FOR WHICH FEDERAL CONSTRUCTION CONTRACTS WERE AWARDED

All three classes of building construction shared in the sharp decrease in activity from 1942 to 1943; additions, alterations, and repairs had the smallest decline and nonresidential building the greatest, so that again in 1943 the volume of residential building was larger than that of nonresidential. In 1944, when construction of war housing was nearly completed, residential permit valuations once more dropped below nonresidential and retained that relative position in 1945.

Five leading cities.—New York City[8] led all other cities for 21 years (1921–41) with respect to the dollar volume of permits issued for building construction. In 1942, however, New York dropped to third place, and in 1943 it did not even appear among the five leading cities. Chicago moved into the lead in 1942 and remained there in 1943; Los Angeles ranked first in 1944 and 1945.

New Orleans, Oakland, and Houston, in 1943, 1944, and 1945, respectively, were among the leading five for the first time within the 2½ decades under survey. Construction of enormous aircraft and shipbuilding facilities accounted for the greatest portion of increased activity in New Orleans and Oakland. Houston came to the fore in 1945 mainly because a huge Navy hospital building program got under way in the first part of the year and a spurt in private commercial building took place as soon as construction controls were lifted in the latter part of the year.

New dwelling units.—Estimates of the number of new dwelling units for which permits were issued in the 257 cities, each year from 1910 to 1945, are presented in table 7. This series provides a reliable measure of year-to-year fluctuations in urban residential construction during the decade which included World War I. Since that time, however, the urban population of the country has been growing at an increasingly greater rate than in the 257 cities. Other biases inherent in fixed samples have also affected this series. For the period commencing with 1920, when these biases become noticeable, more reliable estimates of fluctuations in residential construction will be found in tables 13 and 14, which show the number of new dwelling units started in all urban and rural nonfarm areas.

Permits were issued for more new dwelling units in the 257 cities in 1941 than in any other year after 1929. Although the total of the 232,000 homes shown in table 9 for 1941 was over 11 times that for the low year 1934, it was only about half the volume for each year 1923 through 1926. By 1944 the number had dropped to only a little over a fourth of the 1941 figure, but was still 3 times the 1934 volume. There was a reversal of the down-trend in 1945, particularly in the last quarter of the year when wartime restrictions on all construction were lifted. The total in 1945 was 23 percent higher than in the preceding year.

---

[8] Data for New York City are not exactly comparable throughout the years. From 1921 through 1944 figures presented here are based on applications iled rather than on permits issued. For the years 1942 through 1944 large rojects which were definitely determined to represent postwar plans have een omitted. Figures for 1945 are based on inspection records and repreent work actually started.

Though the Bureau of Labor Statistics index of residential rents moves within a narrower range than the index of new dwelling units for which permits were issued, it follows approximately the same cyclical phases, except in wartime. For example, in 1942 the rent index reached a 10-year high and remained at almost that level through 1945, whereas the index of new dwelling units decreased sharply in each year from 1942 through 1944. Increased demand, coupled with curtailment of all but the most essential building, tended to push up rents. Undoubtedly, without rent control initiated with the Emergency Price Control Act of 1942, the rent indexes for that and following years would have been considerably higher.

TABLE 9.—*Estimated number of new family dwelling units for which permits were issued in 257 cities, by type of structure, 1921–45*[1]

Year	Number of new family dwelling units in—				Percent of new family dwelling units in—		
	All types of structures	1-family structures	2-family[2] structures	Multi-family[3] structures	1-family structures	2-family[2] structures	Multi-family[3] structures

1944	63,711	48,838	7,342	7,531	76.7	11.5	11.8
1945	78,173	61,349	6,386	10,438	78.5	8.2	13.3

[1] Includes number of new family dwelling units in the 257 cities for which Federal construction contracts were awarded.

[2] Includes 1- and 2-family dwellings with stores.

[3] Includes multifamily dwellings with stores.

Single-family houses formed a higher proportion (79 percent) of the new dwellings in the 257 cities in 1945 than in any other year of active building shown in table 9. Two-family and multifamily dwellings, which were relatively popular during most of the 1920's, made up only 8 percent and 13 percent, respectively, of the total in the last war year.

All urban areas, 1942–45

For the period beginning with 1942, the first year after the United States entered World War II, detailed estimates of city building construction are available for all urban areas of the country. Prior to 1942, data presented were a compilation of building permit reports received from a number of cooperating cities. The Bureau of Labor Statistics began the regular collection of these data in 1920, at first including only the larger cities. Coverage kept expanding until (beginning in 1942) the number of cities reporting contained between 80 and 85 percent of the entire urban population, providing sufficient information to form the basis for total urban estimates.[9] At present, more than 2,500 cities cooperate.

The urban area, by Census definition, comprises all incorporated places with a population of 2,500 or more in 1940 and, by special rule, a small number of unincorporated civil divisions. Non-Federal (private, and State and local government) urban building construction is estimated from the building-permit records which are collected by the Bureau directly from local building officials in every State except Illinois, Massachusetts, New Jersey, New York, North Carolina, and Pennsylvania, where State departments of labor collect and forward the data to the Bureau. Estimates of federally financed building construction in urban areas are made from the notifications of construction contracts awarded, which are obtained by the Bureau from other Federal agencies.

Valuation figures, the basis for statements concerning value, are derived from estimates of construction cost made by prospective builders when applying for permits to build, and the value of contracts awarded by the Federal Government. No land costs are included. Unless otherwise in-

---

[9] The method of estimating the total urban building volume is essentially the same as that used to obtain the housing volume in all urban areas, which is explained on pp. 28 and 23.

[1] Includes value of building construction for which Federal contracts were awarded in urban areas.

dicated, only building construction *within the corporate limits* of cities in urban areas is included in the tabulations in this section.

Comparison by type of building.—Permits issued and contracts awarded for new buildings as against additions, alterations, and repairs, represented 90 percent of the total valuation of all urban building construction in 1942, compared with 81 percent in 1943, 71 percent in 1944, and 76 percent in 1945. In contrast to the sharp drop (58 percent) in new construction from 1942 to 1943, valuations of additions, alterations, and repairs as a whole decreased only 14 percent. From 1943 to 1944 new construction continued downward another 23 percent, while addition, alteration, and repair valuations rose 32 percent. Both categories increased from 1944 to 1945—new construction by 90 percent and additions, alterations, and repairs by 50 percent.

Separating the residential additions, alterations, and repairs from the nonresidential, it is significant that there was a rise of 10 percent in valuations in the former between 1942 and 1943, but a decrease of 29 percent in the latter. In the last 2 years of the war, however, both residential and nonresidential additions, alterations, and repairs increased. To some extent, the continued rise from year to year in valuations of residential additions, alterations, and repairs reflects increased emphasis by the National Housing Agency on using existing structures for housing in-migrant war workers. On the other hand, the decline of nonresidential addition, alteration, and repair valuations in 1943 was probably due in part to more extreme reductions for nonresidential than residential building repairs under WPB Conservation Order L–41, issued in April 1942.

In 1944, substantial increases were reported in valuations for additions, alterations, and repairs on both residential and nonresidential buildings. The cumulating volume of old buildings in need of repair, as less new construction was started, probably resulted in greater leniency in authorizing maintenance and repair work on commercial and industrial buildings. In 1945, owing to revocation of the construction limitation order in the last quarter of the year, the valuation figures rose even more sharply—39 percent for residential and 59

Includes value of new nonresidential buildings for which Federal contracts were awarded in urban areas.

[2] Includes stables and barns.

percent for nonresidential additions, alterations, and repairs.

Of the new building total in 1942, 62 percent consisted of nonresidential construction, chiefly because the federally financed industrial facilities program was then at its peak and the War Production Board drastically curtailed the volume of privately financed residential construction early in the year. By the end of 1942, the bulk of the industrial facilities program was under way; consequently, in 1943 well over half the new building valuation was for residential construction. Nonresidential building valuations maintained the same dollar volume in 1944, but residential construction continued to decline. Both types of building nearly doubled in the following year, but nonresidential comprised 56 percent of all new building valuations in both 1944 and 1945.

The valuation of urban nonresidential buildings financed with Federal funds dropped 74 percent from 1942 to 1943, and continued to decline, though not so markedly, in 1944 and 1945. Nonfederally financed building also decreased in 1943 (more than 50 percent), but the following year, it turned upward; and in 1945 the dollar volume was almost 3 times greater than in 1944.

Factory buildings, both federally and nonfederally financed, accounted for most of the fall in nonresidential valuations from the 1942 peak, and figured largely in the sharp recovery in private nonresidential building after VJ-day. Privately financed stores and warehouses, office buildings, garages and service stations, schools and libraries, and public utility buildings, followed the same general movement as all new nonresidential building financed with non-Federal funds. The valuation of institutional buildings, on the other hand, was maintained at approximately the same level throughout the war years, chiefly as a result of the hospital program of the Federal Works Agency. As a result of increased recognition of the importance of recreation facilities and community centers in crowded war production areas, amusement and recreation building was the only major type of nonresidential

[1] Includes number of new family dwelling units and value of building construction in urban areas for which Federal construction contracts were awarded. Estimates for 1929 through 1941 were derived by applying link relatives to data obtained from all reporting cities, the number of which increased steadily each year to almost 2,500 in 1941; figures for 1942 onward were derived by expanding a carefully stratified sample of approximately 3,000 reporting cities to estimate for all urban areas.

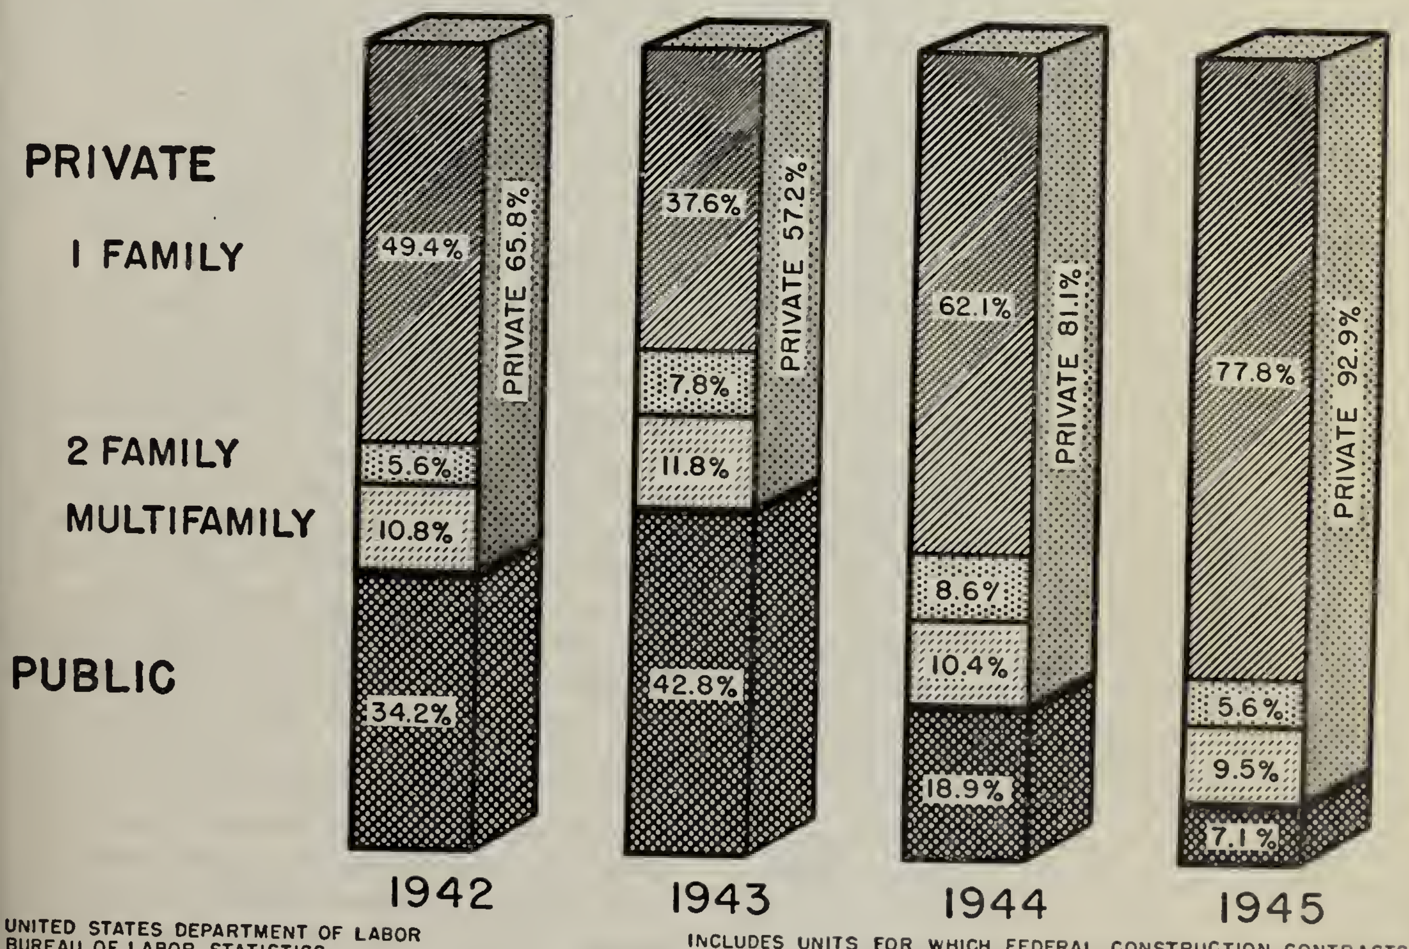
construction which showed an increase in dollar volume in each of the 4 years under discussion.

Permits were issued in urban areas for proportionately fewer private single-family homes in 1943 than in any of the other war years. (See chart 7.) This shift toward two-family and multifamily dwellings (which comprised about a third of all private units in 1943) was caused principally by increased construction of war rental housing under section 608, title VI, of the National Housing Act. Section 608 was added to the act in May 1942, and authorized the insurance of mortgages on large-scale rental projects for war workers. It made liberal financial arrangements available for multifamily rental projects, "having in mind the economies in use of critical material which generally are represented in this type of construction as compared with single-family dwellings."[10] By 1945, less than a sixth of the privately financed units were in two-amily and multifamily structures, and private ingle-family houses comprised well over three-ourths of all new units (both public and private) or which permits were issued or construction ontracts awarded in urban areas.

CHART 7

NUMBER OF NEW URBAN DWELLING UNITS FOR WHICH PERMITS WERE ISSUED

DISTRIBUTION BY SOURCE OF FUNDS AND TYPE OF STRUCTURE



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

INCLUDES UNITS FOR WHICH FEDERAL CONSTRUCTION CONTRACTS WERE AWARDED.

The proportion of urban dwellings which were ublicly financed was also greatest in 1943—over two-fifths. In 1945 public housing accounted for less than a tenth of the total, largely as a result of prompt action on the part of the Federal Public Housing Authority in canceling as many war housing construction contracts as possible the moment the end of the war became imminent.

---

[10] Ninth annual Report of the Federal Housing Administration, for the year ending December 31, 1942 (p. 23).

Comparison by months.—The monthly volume of urban building construction, for which permits were issued or construction contracts were awarded during the years of World War II, reached its peak of 332 million dollars in February 1942. In April, when the War Production Board issued Conservation Order L-41 halting all nonessential construction, permit valuations were only slightly under the peak. By August 1942 the volume was about half the February high, and during the rest of the year and all of 1943 it remained almost constant at slightly over 100 million dollars a month. In 1944, the monthly average was a little over 90 million dollars; and January 1945 valuations of 66 million dollars were the lowest for any month during the entire war period. From that date on there was an almost continuous upward movement in monthly valuations. Seasonal influences in the earlier months of 1945; VE-day in May, with subsequent partial relaxation of controls over construction; VJ-day in August, clearing the way for total reconversion; complete removal of construction limitation orders in October—all played a part in causing urban building construction to more than quadruple by the end of the year. The December 1945 total of 304 million dollars was only 9 percent under the wartime high.

Residential construction volume varied from 127 million dollars in February 1942 to about a ninth of that amount (15 million dollars) in January 1945. Nonresidential building showed about as great a fluctuation—monthly totals ranging from a peak of 226 million dollars in July 1942 to 26 million dollars in February 1944. The volume of additions, alterations, and repairs, on the other hand, moved within a much narrower range than valuations for new buildings. From the low (12 million dollars) reported in January 1943, the rise in addition, alteration, and repair work was almost constant, except for seasonal variations, and reached the peak (58 million dollars) for the 4 years in October 1945.

The relative importance of the Federal war construction program in the monthly volume of urban building construction was considerably less after 1942. In 1942 Federal valuations accounted for more than half the urban total, in each of 9 months, and in May and July they were much more than twice the non-Federal valuations. In contrast, from April 1943 on, the non-Federal exceeded Federal figures. By December 1945, Federal building valuations (2 million dollars) were only a very small fraction of non-Federal valuations (302 million dollars).

New Housing Units in Nonfarm Areas

Estimates of new housing construction—ordinarily comprising the largest segment of total building construction (discussed in the preceding section) —are made by the Bureau of Labor Statistics for the entire nonfarm area. The dwelling units covered are housekeeping units in new structures. Units provided by conversion of existing structures at the original site, or nonhousekeeping units such as those in dormitories, barracks, rooming houses, or hotels, are excluded.

Estimating dwellings started

The "nonfarm area" consists of all urban and rural nonfarm places. The urban designation, as previously stated, is applied to all incorporated places with a population of 2,500 or more in 1940, and by special rule, to a small number of unincorporated civil divisions. Rural nonfarm housing construction includes all but farm homes in unincorporated areas and incorporated places of less than 2,500 population.

A permit to build is required in the majority of cities and in many rural incorporated and a few unincorporated areas. The size, and the builder's estimate of the cost, of the proposed structure are usually recorded on these permits, thereby providing a clear indication of the volume of building to be carried on in the locality. The Bureau receives summaries of building-permit records not only from the cooperating cities previously mentioned, but also from 1,700 rural incorporated places, and about 350 unincorporated areas—that is, from practically every place in the Nation that requires a permit to build.

Using the building-permit reports as a basis, an estimate of the monthly volume of privately financed housing in urban areas is made first and then combined with a similar estimate for rural nonfarm places. To derive the urban estimate, the cities reporting building-permit data to the Bureau are arrayed by State, population-size group, and location inside or outside a metropolitan district; the volume and value of residential building during the month is summarized for each class of place. The estimate for all urban areas in the country is prepared by the simple method of applying to the volume of housing reported for each type of place, the ratio of the total number of such places in the country to the number reporting that month. The ratio is usually 1 for places of 25,000 population or over, because reports are received monthly from virtually all of these. For places of 5,000 to 25,000 population the number of reports is great enough so that the multiplying figure is seldom over 3, and for places of 2,500 to 5,000 population it is rarely over 8.

The estimates are further adjusted for lapsed building permits and time lag between issuance of permits and start of construction, beginning with 1945, when these influences became really significant. Prior to 1945, the issuance of a building permit was almost assuredly a sign that construction would be started immediately. Information on lapse and lag in building permits is derived from periodic surveys in representative areas over the entire country.

The volume of rural-nonfarm housing started prior to 1945 was determined with the use of a bench-mark estimate for each geographic division as of the last quarter of 1939, and a ratio of rural-nonfarm to urban residential building, as derived from detailed housing enumerations made by the Bureau between 1940 and 1942 in 138 defense areas. The bench mark and ratio were used, together with trend information revealed by the volume of hous-

BUREAU OF LABOR STATISTICS 1930-1945

ng in the rural-type places reporting building per- nit data to the Bureau each month, to derive the stimate of rural-nonfarm housing started.

The current method of determining the amount f rural-nonfarm housing started, beginning with 945 data, is to apply to the estimate for all urban laces the ratio of the number of units started in ie rural-nonfarm areas to the number in urban aces in a carefully selected group of 90 repre- ntative areas. The rural-nonfarm estimate is ien added to the urban estimate to obtain the gure for the entire nonfarm area.

Data on publicly financed units are enumerations rather than estimates. The number and location of public units started are reported to the Bureau monthly by the agencies awarding the contracts or performing the work, and are added to the estimates for privately financed units to obtain a total of all nonfarm housing started during the month.

Monthly estimates of the number of new family dwelling units started in all urban and rural-nonfarm areas are available for the period beginning with 1939 (table 15); annual figures for the nonfarm area as a whole date from 1910 (table 13).

Trends from 1910 through 1945

The wide range over which construction of new nonfarm housing has varied in the 36-year period from 1910 through 1945 is shown in table 13. The annual volume dropped from a total of 475,000 units started in 1910 to 120,000 in the war year 1918, increased to 937,000 in 1925, the highest level recorded to date, declined again to the depression low of only 93,000 units in 1933, and recovered to a total of 715,000 in 1941, just before the United States entered World War II. The 1944 total (169,000) was the low point for the war years, but by 1945 the annual volume had increased again to 226,000.

Another indication of the year-to-year variations in the amount of new housing started in nonfarm areas may be seen in chart 9. During 1925, for example, the rate of construction was so high that 11¼ dwellings were started for each 1,000 of population, compared with only 1 in 1933, 7 in 1941, and 2¼ in 1945.

World Wars I and II had similar effects on the number of dwellings started in nonfarm areas. In 1917, as in 1942, the volume of new units declined sharply and continued to decline through the second year of the United States' active participation in the war, as strict priority controls were applied to conserve scarce labor and materials. The rate of decline was much greater, however, in 1917–18 than in 1942–43. The reason for this was that during the Second World War, there were larger numbers of dislocated people, because of vastly greater production needs, more drastic shifts in industry distribution, and more extensive mushrooming of new war plants in nonindustrial areas. Thus, construction of a considerable volume of new homes was required to house war workers, and the Federal Government was obliged to participate actively in providing emergency housing. Well over a third of all new units started during World War II were federally financed, whereas very little housing was federally financed during World War I. The urgent need for war housing and Federal participation in the program resulted in a less marked decline in residential construction during World War II than many had anticipated.

In fact, housing units financed with public funds—most of which were defense or war housing of a temporary nature—increased more rapidly than private housing from 1939 to 1942. In 1939, 57,000 units, or only about a tenth of the new dwellings in

[1] Data for 1920–29 are from National Bureau of Economic Research; data for 1910–19 and 1930–45 are from Bureau of Labor Statistics and are based primarily on building permits issued and Federal construction contracts awarded. No breakdowns are available from 1910–19.

[2] Urban and rural nonfarm classifications for years 1920–29 are based on 1930 Census; for years 1930–45, on 1940 Census.

[3] Includes 1- and 2-family dwellings with stores.

[4] Includes multifamily dwellings with stores.

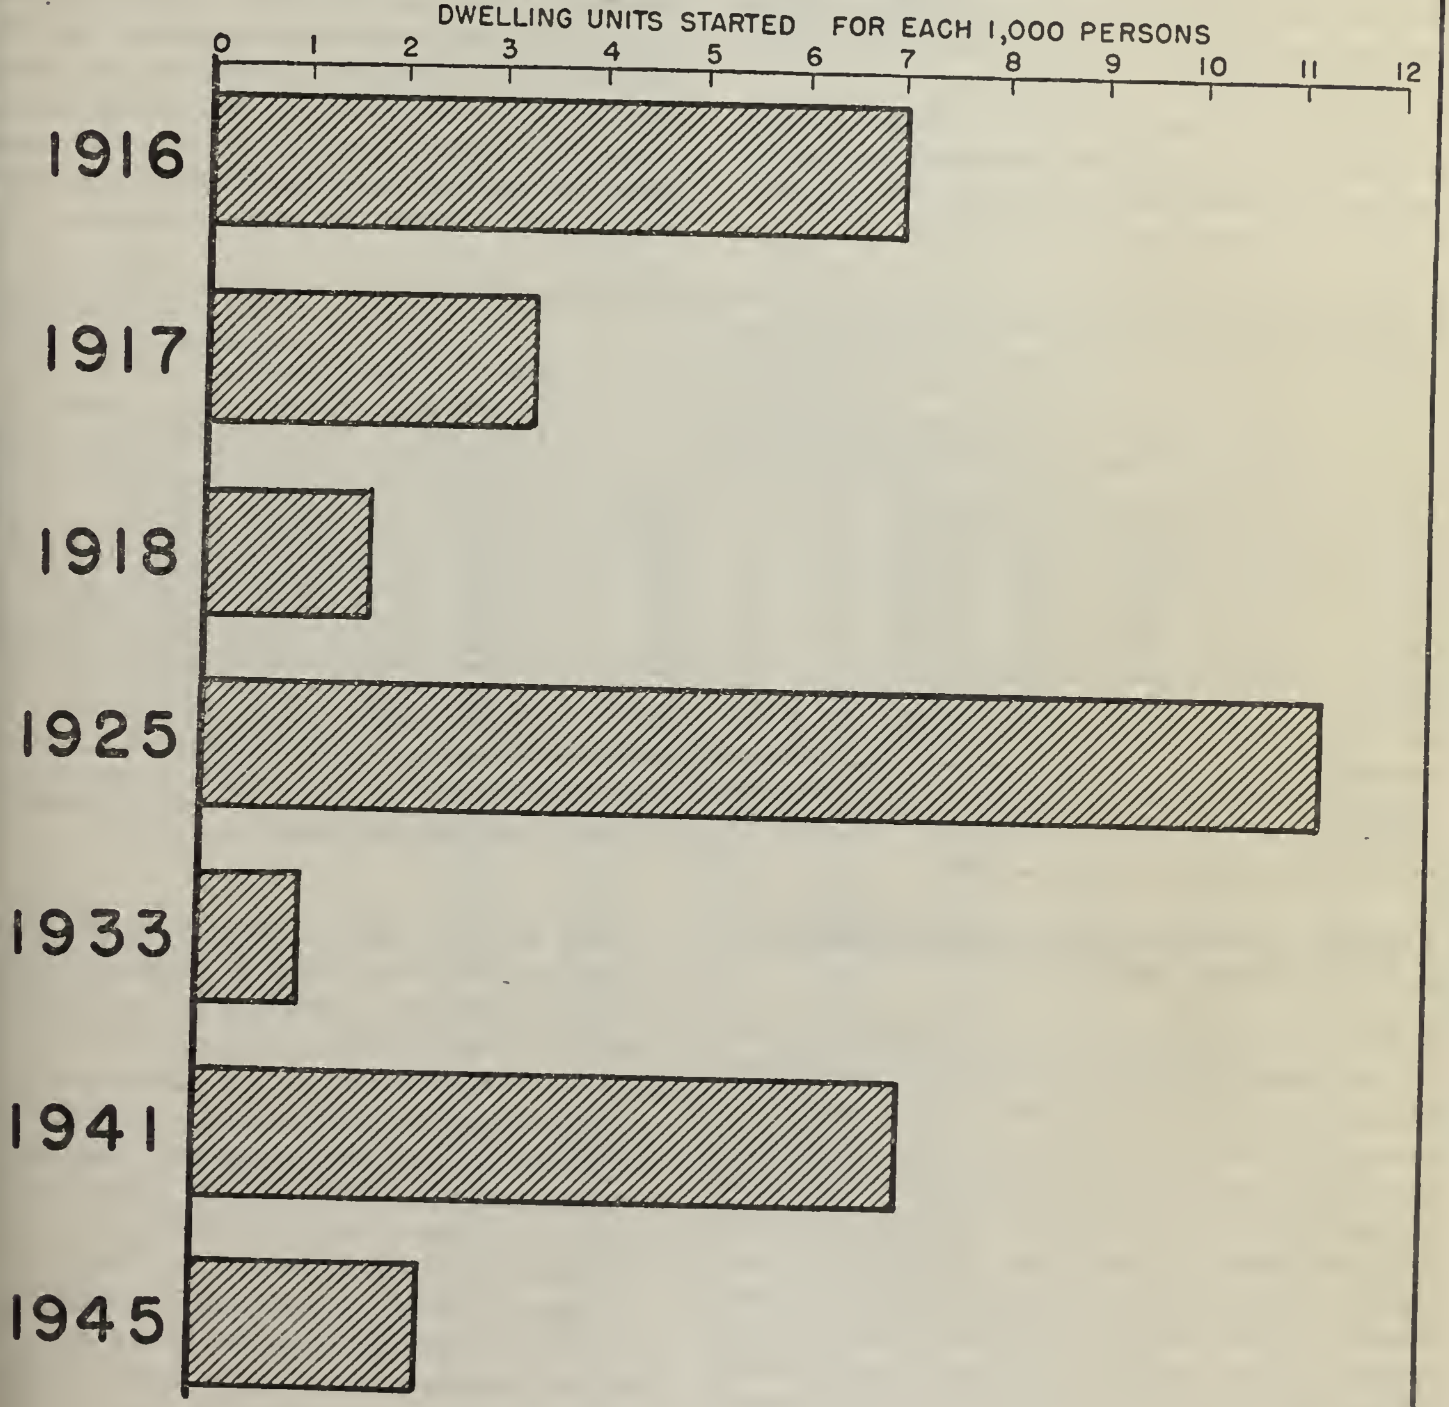
[5] In 1945, in order to determine the number of dwelling units actually started, adjustments were made for lapsed building permits and time lag between issuance of permits and start of construction. Such adjustments were not necessary in previous years, since lag and lapse in building permits were not significant then. Adjusted 1945 figures not available for dwelling units by type of structure.

[6] Unadjusted figures for 1945 represent the estimated number of dwelling units for which permits were issued and Federal construction contracts awarded. Compare with tables 26, 29, and 33.

CHART 9

NONFARM HOUSING IN RELATION TO POPULATION

SELECTED YEARS



UNITED STATES DEPARTMENT OF LABOR
BUREAU OF LABOR STATISTICS

Source: BUREAU OF CENSUS ESTIMATES FOR 1944 AND 1945 CIVILIAN POPULATION; OTHER YEARS, STRAIGHT-LINE INTERPOLATION OF CENSUS FIGURES.

nonfarm areas, were publicly financed; by 1943, the proportion was nearly half the total. During the 5-year period 1939–43, over half a million new units were started with public funds, nearly 200,000 of which were begun in 1942 alone. After that, the need for war housing in critical areas declined, and construction of new public units fell off until, in 1944, less than a fifth (18 percent) of all new dwellings were publicly financed. In 1945, the proportion was only 8 percent, or 18,000 units.

In spite of the large Federal program to provide war housing, private builders started the bulk of the residential building in the defense and war years. In the 5 years between July 1940 (when housing was first coordinated with defense activities) and August 1945 (the end of the war) 1,625,000 privately financed units were put under construction, compared with 557,000 public units. Of the private units, 619,000 were started in 1941—the best home-building year since the boom of the 1920's.

The volume of private dwellings dropped rapidly during the following 3 years, because of acute shortages of both building materials and labor. By 1944, the annual total was only 139,000 units, less than a fourth of the 1941 figure and the smallest annual volume in a decade. In 1945, however, there was a 50-percent rise over the previous year in new private housing, and 208,000 such units were started.

[1] Based on permit valuations adjusted for understatement of construction costs. Excludes land and other nonconstruction items commonly included in selling prices.

[2] Value of Federal construction contracts awarded.

[3] Estimates for 1945 have been adjusted to allow for lapsed building permits and time lag between issuance of permits and actual start of construction. It is believed these influences were negligible prior to 1945.

Monthly variations; influencing legislation and regulations, 1939–45[11]

The rise in housing construction which followed the depression years in the 1930's continued after the outbreak of war in Europe, as a result of the increased demand for emergency housing in defense areas and easier financing through the Federal Housing Administration, together with generally improved economic conditions. In 1939, the number of new family dwelling units started in nonfarm areas averaged about 43,000 per month. The monthly figure continued gradually upward in the succeeding year and a half, except for seasonal fluctuations, until it reached over 77,000 in June 1941.

From the high point of 190,800 in the second quarter of 1941, the number of privately financed units started showed a small decline of only 4 percent in the third quarter. The sharp decline (33 percent) from the third to the fourth quarter is explained in part by normal seasonal tendencies and in part by the fact that the growing shortages of strategic materials influenced some builders against starting new construction until Government policy and the supply situation became clarified.

In order to assist private builders operating in areas of acute housing shortage, the Office of Production Management (later the War Production Board) began on September 22, 1941, to grant priorities assistance in obtaining necessary materials. The real need for this type of assistance at that time is shown by the fact that priorities assistance was extended to an estimated 40 percent of al new units started during the first 3 months of 1942

---

[11] For discussion of developments during the first 6 months of 1946, see Monthly Labor Review, January 1947 (pp. 11-23): Trends in Housing During the War and Postwar Periods.

The growing shortages in critical materials, however, foreshadowed the halting of all nonessential residential construction. On April 9, 1942, the War Production Board issued Conservation Order L–41, prohibiting builders to start, without priorities, any new residential construction costing $500 or more (later reduced to $200) during any continuous 12-month period. No priorities were necessary to replace structures "destroyed after December 31, 1941, by fire, flood, tornado, earthquake, act of God, or the public enemy." In addition, priority assistance was restricted to units with a sales price not to exceed $6,000 or a shelter rental not in excess of $50 per month. The location of any such construction was also restricted to sites within 2 miles either of the war industry to be served or of adequate public transportation.

Shortly after the start of the defense program, it was recognized that because of the unusual risks involved, private builders would require encouragement in supplying homes for defense workers in many areas. Consequently, Congress in March 1941 added title VI to the National Housing Act, which governs the operations of the Federal Housing Administration. This amendment allowed liberal mortgage insurance terms to builders who would provide low-cost housing to war workers in specific areas designated by the President.

During 1941 only an estimated 27,800 of the estimated 220,400 FHA insured units on which construction was started were insured under title VI. During 1942, however, private builders took full advantage of the liberal terms offered, with the result that an estimated 118,900 units, or 72 percent of the 165,700 FHA units started, were under title VI (114,600 under section 603, the March 1941 enactment, and 4,300 under sec. 608, added to the title in May 1942 to provide insured financing of war rental housing). Housing insured under title VI reached peak in 1943 when 145,500 units, or almost all of the FHA starts, came under that title (125,500 under sec. 603, and 20,000 under sec. 608). Insured under titles I and II were 192,600 units started during 1941, 46,800 units started in 1942, and less than 700 in 1943. In 1944, all but 200 of the 93,300 units started were insured under title VI,

---

[1] Estimates are based upon building permits issued and Federal construction contracts awarded. Data for 1945 have been adjusted to allow for lapsed building permits and time lag between issuance of permits and start of construction. It is believed these influences were negligible prior to 1945.

and by 1945, the estimated 41,200 starts were divided more equally—17,300 under title I and II; 23,900 under title VI.

Notwithstanding that private builders began to curtail their operations late in 1941, their activity was not seriously affected until the second quarter of 1942 when Conservation Order L–41 was issued. The 81,100 private units started during that quarter were about 25 percent less than during the preceding 3 months and almost 60 percent less than during the corresponding quarter of 1941. Private activity continued to decline thereafter, reaching a low of 26,000 units in the last quarter of 1944.

Although the number of privately financed dwellings started dropped substantially in the second quarter of 1942, the total nonfarm volume actually increased (from 138,500 units in the first quarter to 166,600) because public housing was at peak. In fact, the 85,500 publicly financed units started in the second quarter of 1942 exceeded the private volume. Public housing was fairly well sustained throughout 1943, but it too dwindled in 1944. The low point was reached in September 1945.

Early in 1940, when the possibility of housing shortages began to threaten the defense program, Congress acted to utilize the organization of the United States Housing Authority to avert this danger by authorizing it to provide homes for military personnel and defense workers (Pub. L. 671, 76th Cong.). As the war housing program grew in magnitude, other agencies, notably the Federal Works Agency which was charged with dministration of funds appropriated under the anham Act, entered this field of activity. By ebruary 1942, there were 16 different Federal gencies concerned with war housing construction, nd on February 24, 1942, the National Housing gency was created by Executive order, in order to onsolidate these activities. The Federal Public ousing Authority of the National Housing Agency ecame responsible for the construction of all ederally financed nonfarm housing except that uilt on military reservations. For various reasons some projects were assigned for construction to other agencies, but most projects were constructed under the direct supervision of the Federal Public Housing Authority or of local housing authorities.

Funds for publicly financed war housing were authorized through six major acts and by transfer of funds authorized by the Congress from other branches of the Government.

The principal sources of these funds were (1) the Lanham Act, as amended (Pub. L. 849, 76th Cong.), which authorized the National Housing Administration to provide war housing and authorized funds to be appropriated for this purpose; (2) the temporary shelter acts (Pub. L. No. 9, No. 73, and No. 353, 76th Cong.) which appropriated money specifically for temporary housing; (3) USHA efense Amendment (Pub. L. 671, 76th Cong.) hich authorized use of funds available to the nited States Housing Authority for war rental using; (4) Defense Homes Corporation, loans btained from the RFC to build permanent housing r use of war personnel during the emergency, with e intention of selling as expeditiously as possible; d (5) the Army-Navy appropriation measure ub. L. 781, 76th Cong.) which appropriated funds provide rental housing for families of personnel Army and Navy bases.

At the close of 1944, $2,340,712,028 had been mmitted or allotted for war housing from the tal public funds ($2,355,348,894) made available, ving $14,636,866 to carry on the program.

On April 25, 1945, and prior to the termination of hostilities, the Congress appropriated $84,373,000 for war housing to be constructed under the provisions of title I of the Lanham Act. However, the suspension of war housing projects after VJ-day affected savings totaling $77,727,000.

Title V was added to the Lanham Act by Public Law 87, approved June 23, 1945. This law authorized the Federal Works Administrator to provide housing for distressed families of servicemen and for veterans and their families who were affected by evictions or other unusual hardships in those areas where their needs could not be met through utilization of the existing housing supply. Title I funds were made available for title V purposes.

Additional funds for carrying out the provisions of title V of the Lanham Act were provided by

---

stimates are based upon building permits issued and Federal construction ntracts awarded. Data for 1945 have been adjusted to allow for lapsed building permits and time lag between issuance of permits and start of construction. It is believed these influences were negligible prior to 1945.

Congress in December 1945 through two measures; the Mead-Lanham resolution, Public Law 292, which authorized appropriations of $160,000,000, and the first deficiency appropriation for the fiscal year 1946 (Public Law 269), which appropriated $191,900,000 for veterans housing.

No new permanent housing could be constructed under title V as amended. Temporary housing only could be provided by moving existing temporary housing from areas where the war need had passed to areas where such housing was needed for veterans, or by converting surplus Federal structures or facilities into temporary housing for veterans. Stimulated by the initiation of this program, the monthly volume of publicly financed dwellings started, began to recover slightly in the closing months of 1945.

From a peak of 59,600 in 1941, the monthly average of total nonfarm starts dropped to 41,400 in 1942 and to 29,200 in 1943, reaching a low of 14,100 in 1944. By 1944 the war housing program for in-migrant war workers (H–1 housing) had passed its peak. To meet general civilian needs and to establish the pattern for the expected transition period, the National Housing Agency initiated two new programs: H–2 housing, which permitted construction of dwelling units of up to $8,000 valuation under certain conditions of community hardship; and the H–3 program, which was designed to relieve individual hardship cases.

The H–2 program, however, was brought up short at the start of 1945 by further demands of war. After the German counter attack in December 1944, the Area Production Urgency Committees of the War Production Board turned down most applications to start H–2 housing. It was feared that the Nation did not have the manpower to build houses and also to keep war production going at top speed. H–3 housing went forward under blanket authorization granted by most APUC's, up to $10,000 construction cost.

With the defeat of Germany in May 1945 the tempo of housing activity under the H–2 and H–3 programs was stepped up, and the number of nonfarm dwelling units started advanced from 27,900 in the first quarter to 55,200 in the second quarter of 1945. These transitional programs also paved the way in the period immediately following Japan's surrender; third quarter starts were sustained at about the same level (57,400).

The lifting of all wartime controls in October resulted in an unprecedented increase in home building, almost all of which was privately financed. Contrary to the usual seasonal slump during the fall and winter months, the total number of nonfarm dwelling units started reached 85,200 in the fourth quarter, an increase of 48 percent over the preceding 3 months.

Trends in Private Building Construction Costs

The Bureau of Labor Statistics does not compile a comprehensive index of construction costs. It makes a composite index of average hourly earnings on private building construction and of wholesale construction material prices, which, while incomplete, gives an approximation of changes in construction costs. The composite index measures only reported changes in labor and material costs and does not reflect construction cost changes resulting from variations in the efficiency of labor and management, in competitive markets, in overhead costs, nor does it reflect the payment of black-market prices.

Further indications of fluctuations in construction costs (of residential building only) may be obtained from two other series, one showing the average permit valuation of all types of family dwellings in 257 cities, and the other showing the average "estimated construction cost" for private single-family dwelling units in nonfarm areas.

The permit valuation figure is simply an average of the estimated construction cost data recorded on the building-permit reports received by the Bureau together with the value of the Federal construction contracts awarded in the 257 cities.

For a number of reasons the estimates of construction costs which are given by builders when applying for building permits generally understate actual costs. The results of a prewar study mad by the Bureau indicate that actual costs (i.e., cos of labor, material, and the builder's overhead and profit chargeable directly to the constructio project, but excluding cost of land and site improvements) averaged 15.5 percent more than the value ations entered on permit records. More recent surveys revealed that in the period September-December 1945 the understatement of permit valuations was around 25 percent. Consequently, to obtain the "average estimated construction cost" series, the valuation figures recorded on the building permit reports for years prior to 1941 were increased by 15.5 percent. From 1941 on the percentage added to the permit valuation was gradually increased, on practically a straight-line basis, until it reached 25 percent in September 1945.

In interpreting both of these series of averages, it should be noted that they do not represent fluctuations in the cost of building identical units of housing, but show fluctuations only in the estimated construction costs of all those units for which permits were issued.

Composite Index

Construction costs for privately financed buildings, as measured by the composite index of average hourly earnings and wholesale prices of building materials, rose 40 percent between 1934 and 1943. After remaining on a comparatively even keel during the 3-year period 1934–36, sharp rises in 1937 in both labor and material charges resulted in a 10-percent increase in costs. Although union wage rates, which had gradually increased after 1934, rose 9 percent between 1937 and 1938, average hourly earnings remained virtually unchanged. This was caused primarily by a decline of almost one-third in the volume of private nonresidential building on which higher wage rates generally prevail. Furthermore, as a result of a 5-percent decrease in material prices in 1938 the composite index was 3 percent lower than in 1937.

TABLE 17.—*Indexes of construction costs and expenditures for new private building, 1934–45*

Year	Index numbers (average 1935-39 = 100)						
	Union hourly wage rates in building trades	Average hourly earnings on private building	Wholesale prices of building materials	Composite of earnings and prices[1]	Expenditures for new private building		
					Total	Residential	Nonresidential
1934	88.8	90.8	96.2	94.1	38.4	26.6	59.5
1935	89.8	93.0	95.2	94.4	53.6	48.9	61.8
1936	93.1	94.1	96.8	95.8	86.8	83.2	93.2
1937	99.5	103.1	106.2	105.0	115.9	101.0	142.4
1938	108.4	103.7	100.8	101.9	107.2	111.2	100.0
1939	109.1	106.4	101.0	103.1	136.6	155.6	102.7
1940	110.8	109.4	105.8	107.2	159.4	173.3	134.5
1941	114.9	115.3	115.2	115.2	200.3	203.5	194.5
1942	122.0	131.1	123.0	126.1	91.9	96.8	83.1
1943	123.0	142.9	124.3	131.5	41.5	47.8	30.4
1944	123.9	150.6	128.9	137.3	41.7	39.4	45.8
1945	126.5	157.4	131.5	141.5	79.3	49.3	132.7

[1] Based on average hourly earnings in private building construction and wholesale prices of building materials. In 1939 labor constituted 38.6 percent and material 61.4 percent of the composite average. Changes in construction costs resulting from variations in the efficiency of labor and management, in competitive markets, and in overhead costs are not reflected in this index.

Increases in both basic wage rates and the relative amount of overtime worked at premium rates, in addition to rising material prices, notably for lumber, resulted in an increase of 24 percent in construction costs between 1938 and 1942. Brisk competition for construction workers from publicly financed war construction projects, coupled with the demands from war industries and the military services, caused virtually all private builders to pay wages and overtime penalties equivalent to those required under union agreements. Some measure of the extent to which increased overtime and the shift to the equivalent of basic union wage rates affected building costs between 1940 and 1942 may be seen by comparing the 10-percent increase in union wage rates with the 20-percent rise in average hourly earnings.

TABLE 18.—*Average hourly and weekly earnings and weekly hours worked on private building construction, and index numbers, 1934–45*

Year	Average			Index (average 1935-39 = 100)		
	Hourly earnings	Hours worked per week	Weekly earnings	Hourly earnings	Hours worked per week	Weekly earnings
1934	$0.795	28.9	$22.97	90.8	89.8	81.3
1935	.815	30.1	24.51	93.0	93.5	86.8
1936	.824	32.8	27.01	94.1	101.9	95.6
1937	.903	33.4	30.14	103.1	103.7	106.7
1938	.908	32.1	29.19	103.7	99.7	103.3
1939	.932	32.6	30.39	106.4	101.2	107.6
1940	.958	33.1	31.70	109.4	102.8	112.2
1941	1.010	34.8	35.14	115.3	108.1	124.4
1942	1.148	36.4	41.80	131.1	113.0	148.0
1943	1.252	38.4	48.13	142.9	119.3	170.4
1944	1.319	39.6	52.19	150.6	123.0	184.7
1945	1.379	39.0	53.73	157.4	121.1	190.2

The composite index rose 7 percent between 1940 and 1941 and over 9 percent between 1941 and 1942. In both 1943 and 1944, however, the annual rate of increase was down to 4 percent, partly because wage and price controls were put into effect less than a year after the war started. In 1945 the index was only 3 percent higher than in 1944, owing in part to reductions in overtime work and retention of wage and price controls after VJ-day.

The wholesale prices of building materials rose far less in World War II than during World War I. Comparable figures show a 92-percent rise in wholesale prices of building materials from July 1914 to

[1] Includes the following programs: (1) Programs from regular Federal appropriations, (2) Public Works Administration, (3) United States Housing Authority, (4) Defense Plant Corporation, (5) War Public Works (Lanham Act projects), (6) Rural Electrification Administration (loans).

[2] Computed by dividing reported annual pay rolls and number of man-hours worked during the year by 52. This method is used primarily because hours and earnings on Federal construction projects are reported by accounting months, rather than by calendar months. Thus all contractors do not report for uniform pay periods during any given month; some may include data for 4 weeks and others for 5. In addition, averages in a given month are affected substantially by shifts in the geographic distribution of projects under way, especially when the number of projects in a category is small. Consequently, average hours and earnings cannot be computed accurately on a current weekly basis. Most of the bias resulting from both the reporting procedures and the project location, however, is removed when data for the year as a whole are used to obtain averages.

[3] Hourly earnings when multiplied by weekly hours of work may not exactly equal weekly earnings because of rounding.

November 1918 against a 31-percent increase between August 1939 and August 1945. The effectiveness of price control during World War II may be judged from the fact that, although average prices or all building material rose 23 percent from August 939 to March 1942, the rise in prices from March 942 to the end of hostilities under operation of the General Maximum Price Regulation[12] was only 7 percent.

---

[12] See Monthly Labor Review, March 1944 (p. 640): Market Prices of Building Materials in Two Wars. The General Maximum Price Regulation was issued by the Office of Price Administration on April 28, 1942, and provided that, with certain exceptions, manufacturers', wholesalers', and retailers' prices were to go no higher than the highest price which the respective commodities brought in March 1942.

TABLE 21.—*Average union hourly wage rates in selected building trades, 1934–45*[1]

Trade	Average hourly rate[2]											
	1945	1944	1943	1942	1941	1940	1939	1938	1937	1936	1935	1934

---

[1] Rates for 1943–45 are actual averages computed from a sample of quotations of union wage rates. The Bureau's sample of union wage-rate quotations for early years was heavily weighted by quotations from larger cities. However, cities added from time to time have been smaller and of different geographic distribution and thus current figures more accurately represent union wage rates for the country as a whole. Consequently, rates for years before 1943 shown in this table are estimates from an index of union wage rates in which year-to-year changes have been measured using quotations from identical local unions for each pair of years. These estimates for 1934 to 1942 are lower than those based on the Bureau's changing sample of quotations as published annually in "Union Wages and Hours in the Building Trades."

[2] Representative of rates effective in midsummer.

[3] Average includes selected trades plus others not shown in this table. For other trades and years, see annual Bureau publication "Union Wages and Hours in the Building Trades."

[4] Includes rodmen prior to 1940.

---

[1] These data represent the minimum wage rates agreed upon through collective bargaining between employers and trade unions. Rates shown are those applicable to most types of work. For many cities and trades, agreements provide for lower rates on residential and speculative projects and higher rates for the more hazardous work such as bricklayers on sewer and tunnel work, and painters on bridge, structural steel, and spray jobs, etc. See the Bureau's annual publication "Union Wages and Hours in the Building Trades" for details concerning rates for each occupation.

[2] Jobs over $2,000, $1.375; under $2,000, $1.250.

[3] Jobs of over 1,500 man-hours, $1.750; jobs of under 1,500 man-hours, $1.500.

[4] Contracts under $1,000, $1.380; contracts over $1,000, $1.500.

[5] Contracts under $20,000, $1.375; $20,000 or over, $1.750.

[6] Over $20,000, $1.750; under $20,000, $1.250.

[7] Covers Rock Island and Moline, Ill., and Davenport, Iowa.

[8] Contracts under $15,000, $1.500; contracts over $15,000, $1.625.

[9] Contracts under $20,000, $1.500; contracts over $20,000, $1.625.

[10] Contracts over $3,000, $1.500; contracts under $3,000, $1.250.

Residential construction costs

In response to a general rise in prices, the average construction cost of privately financed single-family dwelling units rose gradually from $3,973 in the first quarter of 1940 to $4,303 in the third quarter of 1941 (table 24). No cost limitation for private war housing prevailed prior to the establishment of the priority system in September 1941, but the limitation of a sales price of $6,000 or an equivalent shelter rent not to exceed $50 a month was established at that time by the Office of Production Management and the Division of Defense Housing Coordination. Immediately after the initiation of this priority system, the average estimated construction cost figure began to drop slightly—to $4,226 in the final quarter of 1941 and to $4,011 in the first 3 months of 1942.

Conservation Order L–41 was issued in April 1942, restricting home building to $500 (later $200), with exceptions, unless priorities were granted. In addition, priorities were issued only where the sales price of a unit did not exceed $6,000. The effects of this order were to force home construction still more into the lower-cost brackets and to decrease further the "average cost" figure to $3,762 in the third quarter of 1942.

Undoubtedly some homes continued to be built in the higher-cost brackets. There are, however, several explanations for this. Homes built to replace those destroyed by fire, tornado, etc., were exempted from L–41. Evasion of priority regulations was present to some degree. Instances are known in which less responsible speculative builders sold basic houses at the maximum price permitted,

TABLE 23.—*Weighted indexes of wholesale prices of building materials, 1934–45*

Year	Index numbers (average 1935–39 = 100)			
	All building materials	Brick and tile	Cement	Lumber
1934	96.2	99.3	102.2	94.1

[1] Base price.

making an extra charge for such essential items as connection to the public water system, but the extent of such practices is not known. Nevertheless, after April 1942, the trend in construction costs was generally downward, indicating the increasing effectiveness of administrative control of housing priorities. The low point was reached in the fourth quarter of 1944 when construction cost averaged $3,223.

In May 1945, construction controls were eased by amendment to L–41; the limitation of $200 on residential building that could be started without permission of the War Production Board was raised to $1,000 in the case of 1-family houses. In addition, more housing was being started in the first part of 1945 under the H–2 and H–3 programs. H–2 housing had a sales limit of $8,000 (compared with $6,000 for H–1 housing, which had predominated previously), and there was no cost limit under the H–3 program. These events influenced average construction cost estimates, resulting in a 17-percent rise between the first and second quarters of 1945 (from $3,554 to $4,167).

Hostilities ended in the third quarter of 1945. Schedules I and II to WPB Order P-55-C (which imposed materials limitations and restrictions on building sizes of approved housing construction) were revoked in September. The withdrawal of L–41 in October automatically removed price ceilings on dwellings which had been built under that order. It also removed price limits for dwellings started thereafter. Home builders were in competition for the limited supply of labor and material available in the housing market. The estimated construction cost per private 1-family dwelling unit, jumped another 18 percent, to $5,307, from VJ-day to the final quarter of 1945.

TABLE 24.—*Change in estimated construction cost of new private 1-family nonfarm dwellings, quarterly, 1940–45*[1]

Year and quarter	Private 1-family dwellings

[1] These figures are based upon builders' estimates of construction cost, exclusive of land and improvements. They do not show change in cost of erecting identical buildings, but reflect the change in estimated costs of all buildings to be erected. Estimates of construction costs should not be confused with market or selling price.

[2] Less than .05 percent.

[3] OPM established system of priority control on residential construction.

[4] Construction Control Order L–41 issued; wage and price controls instituted.

[5] VE-day; construction controls eased by amendment to L–41.

[6] VJ-day; Schedules I and II to P-55-C revoked.

[7] P–55 and L–41 revoked.

Some idea of variations over the years in the cost of erecting residential buildings may be obtained also from table 25. Average permit valuations pe new dwelling unit in 257 cities declined steadil from the 1920's to the depression year 1933, an recovered somewhat in the late 1930's. During th war years, the average valuations of 1-family dwellings followed the same general movement already described for estimated construction costs. In the case of all types of structures, the average permit valuation figure decreased steadily from 1939 to 1943, when it reached the lowest amount recorded within the 25-year period 1921–45. The average valuations for 1-family dwellings decreased more sharply in 1943 than those for 2-family and multifamily dwellings. This was caused largely by the construction of many temporary row-type single-family dwellings under the programs of the Federal Public Housing Authority. By 1945, the average valuation figures for each type of structure, except multifamily, exceeded those for the recovery years 1936–37.

TABLE 25.—*Estimated permit valuation*[1] *per new family dwelling unit in 257 cities, by type of structure, 1921–45*[2]

[1] Includes value of new family dwelling units in 257 cities for which Federal construction contracts were awarded.

[2] This table does not show change in cost of erecting identical buildings, but reflects the change in estimated costs of all buildings to be erected. Land and improvement costs are excluded.

[3] Includes 1- and 2-family dwellings with stores.

[4] Includes multifamily dwellings with stores.

Shifts in Location of Construction Activity in Wartime

The location as well as the volume of construction activity was sharply altered during the war period. Locality changes consisted chiefly of two general types: (1) shifts from densely to more sparsely populated places, and (2) movements from one section of the country to another.

Flow Between Large and Small Places

Urban-rural movements

Housing trends are an indicator of the urban-rural flow of building activity in the war years. Thousands of new homes were built near military or essential industrial establishments, many of which were of necessity located outside of urban areas.

About 39 percent of the new nonfarm houses started in 1941 were located in rural areas, whereas, in 1942 the proportion of rural-nonfarm to all housing had increased to 43 percent. By 1943 it had decreased again to 40 percent. The shift from urban to rural in 1942 and from rural to urban in 1943 reflects mainly the effects of the public war housing program. In 1942, several extremely large projects, notably the Vanport City (Oreg.) project containing almost 10,000 units, were put under construction contract. The large tracts of vacant land necessary for such projects are seldom available in urban areas. Also, the construction of entire communities to serve isolated war activities contributed to the urban-to-rural shift in 1942. Such projects were less prominent in 1943, and it was possible to utilize small vacant tracts in urban areas to a greater extent than in 1942.

In 1944, the proportion of all nonfarm housing to be started in rural areas was down to 32 percent, but there was a slight increase to 36 percent in 1945. Since nine out of ten homes in 1945 were to be

TABLE 26.—*Estimated number and valuation of new family dwelling units for which permits were issued in nonfarm areas, by type of area, size of city, and source of funds, 1942–45*[1]

[2] Includes 1- and 2-family dwellings with stores.

[3] Includes multifamily dwellings with stores.

financed from private funds, it appears that more private owners, too, were tending to build outside city limits. One explanation of this growing trend[13] is that land prices are more reasonable in outlying areas. The increasing development of well-planned neighborhoods with nearby community centers, together with greater availability of quick transportation to downtown districts, is making suburban living more and more attractive.

Size-of-city shifts

Within the urban area also, there were similar movements in building activity between large and small places during the war years. In 1942, 29 percent of the urban building permit valuation figure was reported for cities of 2,500 to 25,000 population;[14] cities in the 25,000 to 100,000 population group accounted for 23 percent and those with more than 100,000 population for 48 percent of the total. The proportions in 1944 for the respective city-size groups were 25, 20, and 55 percent. This shift in building activity from small to large cities is explained partly by the fact that a great part of Federal wartime construction, even within city limits, was near army camps, powder plants, or other war establishments necessarily located in sparsely populated sections of the country. Consequently, the greater proportion of Federal money put into urban building in 1942 influenced the flow of construction in that year away from the larger cities to the smaller places. The reverse was true, of course, in 1944 when most war construction was completed. In 1942 over 60 percent of the dollar volume of urban building was for Federal construction, compared with 32 percent in 1944.

Another cause for shifts between different city-size groups is the varying proportion from one year to another in the types of building construction for which permits are issued. For example, in 1942 only a tenth of urban permit valuations were for additions, alterations, and repair work; whereas, in 1944 this category comprised almost three-tenths of the total. Well over half of all such valuations were, in each year under discussion, reported for cities of 100,000 or more population. Consequently, in a year (like 1944) when the proportion of additions, alterations, and repairs is high relative to the volume of new building undertaken, there is a tendency for the largest cities to be responsible for the greater share of permits issued.

In 1945, when additions, alterations, and repairs accounted for a fourth of all urban building activity and 53 percent of the work was being done in cities of over 100,000 population, those cities reported 49 percent of the total dollar volume of building permits granted. Cities with population from 25,000 to 100,000 reported 22 percent, and those in the 2,500 to 25,000 population group, 29 percent of the total.

Geographic Shifts

Between States

Analysis of the amount of new housing put under construction during the period 1940–45, in comparison with the number of homes already standing in 1940 in each State, gives a clear indication of interstate shifts in residential building in the defense and war years.

The estimated number of new nonfarm family dwelling units for which permits were issued or construction contracts were awarded in the years 1940–45 totaled 2,580,000, about 9 percent of the 29,683,000 units standing in April 1940.[15] Home building during this 6-year period tended to concentrate along the eastern and western seaboards, the Great Lakes, and in the Southwest. These regions were the leading centers of residential construction for two important reasons—(1) they accommodated most of the war activities requiring workers from outside areas, and (2) some of them already accounted for a large portion of existing housing, which made replacement demand greater there than in other localities.

The concentration is shown in chart 10 on page 41. From map' 'A" it is readily apparent that California outranked all other States with respect to the number of new family dwelling units for which permits were issued during 1940–45. California alone was responsible for 419,100 units—16 percent of the total. Texas followed with 175,500 units, or 7 percent. The 10 leading States (California, Texas, Michigan, New York, Ohio, Pennsylvania, Virginia, Washington, Illinois, and Florida) accounted for almost 60 percent of the total, or 1,513,000 units. Of these States, all except Florida, Virginia, and Washington were also among

---

[13] Preliminary results of a survey conducted in 1946 in 90 representative areas bear out the conclusion that there is an increasing tendency to build a greater proportion of nonfarm housing in rural than in urban areas.

[14] Population figures used for grouping cities based on 1940 Census.

[1] Includes estimates of the number and permit valuation of dwelling units in non-permit-issuing (urban and rural-nonfarm) places.

[2] Includes 1- and 2-family dwellings with stores.

[3] Includes multifamily structures with stores.

the 10 highest in regard to the number of dwelling units in existence in April 1940. However, there was a great concentration of military activities in Florida and Virginia and of ship and aircraft construction in Washington, which was responsible for a large amount of homebuilding to accommodate in-migrants.

The number of new nonfarm dwelling units for which permits were issued in each State during 1940–45 as a proportion of the number of dwellings already standing in April 1940 is shown in map "B." This presentation is particularly significant in pointing out areas of in-migrant need, since it neutralizes the factor of replacement demand. For instance, there were more units standing in 1940 in New York than in any other State (3,827,054), and it ranked fourth in the amount of home building during 1940–45; however, the number of dwellings started in that State during the 6-year period was only 4 percent of existing housing, indicating relative stability in wartime population.

On the other hand, in Nevada, which had the fewest units standing (31,993), there was proportionately more housing put under construction than in any other State (29 percent of existing housing). Replacement demand for homes in Nevada was negligible, since there were so few houses in existence. This condition, together with the fact that the population of Nevada increased 45 percent from 1940 to 1945, makes it apparent that most of the new dwellings put under construction during the 6-year period were to take care of families coming into the State from other areas. Reports of Federal contracts awarded in October 1941 for the construction of a 126-million-dollar basic magnesium plant near Las Vegas, which first required numerous construction workers and later many operational employees, further substantiates this conclusion.

As would be expected from the foregoing discussion of nonfarm housing, California was also the leading State in the dollar volume of building permits issued during the war years 1942–45. Over 17 percent, or 1.2 billion of the 7 billion dollar permit valuation figure for all urban areas, was reported for California alone. Michigan and Illinois (each accounting for around 7 percent of the total) ranked second and third, respectively, with 507 million and 468 million dollars.

Not only did California lead in the amount of total permit valuations, but it was in first place with respect to all classes of building construction: New residential building 522 million dollars (21 percent of the 2.5 billion dollars estimated for new residential building in all urban areas); new nonresidential building, 513 million dollars (16 percent of the 3.2-billion-dollar total); and additions, alterations, and repairs, 173 million dollars (13 percent of 1.3-billion-dollar total). Michigan, with 225 million dollars (9 percent of all urban) was second in the new residential building category. Second place for new nonresidential building went to Pennsylvania (250 million dollars, 8 percent of total), and for additions, alterations, and repairs to New York (123 million dollars, 9 percent of all urban).

From Region to Region

The impact of war upon construction activity in different sections of the country is reflected in the altered distribution of new nonfarm housing from

---

[1] Includes number of dwelling units and value of building construction for which Federal contracts were awarded in urban areas.

[2] Includes valuation of dormitories and other nonhousekeeping residential buildings in addition to the housekeeping units shown in the first 2 columns.

TABLE 32.—*Value of contracts awarded and force-account work started on construction projects financed wholly or partially from Federal funds, by State, 1943–45*[1]

State	Value (in thousands of dollars)														
	1945							1944							1943[2]

[1] Projects classified as secret by the military (including atomic bomb production facilities) are excluded.

[2] Data by type by State not available for 1943.

[3] Includes additions, alterations, and repairs.

[4] Includes forestry, railroad construction, heavy engineering, and electrification work.

year to year among the 9 geographic divisions of the United States.

Three regions, the East North Central, South Atlantic, and Pacific, accounted for the greatest number of new nonfarm dwellings for which permits were issued in each year 1940–45. In 1940, the largest share of the new homes, 122,900 units (19 percent of the total nonfarm figure), were to be started in the South Atlantic States. The East North Central and the Pacific States followed in close order, with 106,300 and 104,600 units, respectively.

By 1942, the Pacific States were in the lead with a fourth of all new nonfarm housing (125,200 units), and they continued in first place through 1945. These substantial rises in new housing in the Far

---

[1] Includes estimates of the number and valuation of dwelling units in non-permit-issuing (urban and rural-nonfarm) places.

[2] Includes 1- and 2-family dwellings with stores.

[3] Includes multifamily dwellings with stores.

West reflected the large population increases which took place there during the war years. Thousands of workers, many of them from farms, migrated to the leading Pacific Coast cities to work in airplane factories, shipyards, and other war industries. From 1940 to 1945, the population of the Pacific States increased 25 percent, or 2.4 million. Furthermore, increased employment of the native population enabled more people to afford their own homes or apartments.

In 1945, the employment rise after the end of the war in the nonmanufacturing industries—primarily the services and trades—almost offset the substantial declines in shipbuilding, airframe, and other manufacturing employment on the Pacific Coast following VJ-day. In addition, the housing needs of returning veterans and their families who had been living doubled up more than compensated for any out-migrants who may have left as the war industries shut down. Although the substantial number of 68,200 units, or 28 percent of all nonfarm houses, were to be started in the Pacific States in 1945 (almost four-fifths of them in California alone), the housing shortage remained acute throughout that region.

Only the Western and the Southern States, where most of the military installations were located, showed population increases between 1940 and 1945. The northern part of the country in particular experienced declines, as inductions depleted the civilian population and war workers migrated to new war centers. The Middle Atlantic States

[1] Includes value of building construction in urban areas for which Federal contracts were awarded.

[2] Less than a tenth of 1 percent.

showed a million and a half decrease in population during this period, and the West North Central States declined over a million.

Reflecting increases in population, the South Atlantic States ranked next to the Pacific in the total number of new dwelling units for which permits were issued or contracts awarded in 1945 (43,500). The East North Central States were third with 41,600 units. Housing shortages in those areas had been accumulating throughout the war years for various reasons and remained critical at the end of 1945. In Chicago, for instance, housing shortages were caused by enlargement of the packing and chemical industries, as well as ordnance, the transfer of Federal agencies from Washington, and the expansion of war agencies already in the city. In Detroit, the shortage resulted partly from expansion of the aircraft engine industry. Ohio, the rubber center of the world, with its wartime production of steel, machinery, chemical products, and aircraft, also experienced a housing shortage which was still unrelieved as the war ended.

The smallest proportion of new nonfarm homes in 1945, on the other hand, were to be started in New England—5,500 units, or 2 percent of the national total. This compares with 30,400 units (5 percent of total) in 1940. In that year the Mountain States ranked lowest, with 21,600 new dwellings. Part of the decline in the amount of new housing to be built in New England was owing to a 2-percent decrease in population from 1940 to 1945. Although there was little migration into New England compared with most other regions, mainly because of less new industry, the housing shortage remained acute in 1945 as veterans returned in increasing numbers and principal industrial centers began to convert to peacetime production.

---

[1] Includes value of new nonresidential buildings in urban areas for which Federal contracts were awarded.

[2] Includes factories, navy shipbuilding and repair facilities, army ordnance plants, bakeries, ice plants, industrial warehouses, and other appurtenant buildings, etc.

[3] Includes amusement and recreation buildings, stores and other mercantile buildings, public garages, gasoline and service stations, etc.

[4] Includes churches, hospitals, and other institutional buildings, schools, libraries, etc.

[5] Includes Federal, State, county, and municipal buildings, such as post offices, city halls, fire and police stations, army barracks, naval stations, etc.

[6] Includes railroad, bus and airport buildings, round houses, radio stations, gas and electric plants, public comfort stations, etc.

[7] Includes private garages, sheds, stables and barns, and some other buildings not elsewhere classified.

APPENDIX.—*Building Construction Reported to the Bureau of Labor Statistics, by City and by Class of Construction, 1943, 1944, and 1945*

Letter of Transmittal

United States Department of Labor,
Bureau of Labor Statistics,
Washington, D. C., February 18, 1948.

The Secretary of Labor:

I have the honor to transmit the Handbook of Labor Statistics, 1947 Edition. This is the sixth in the handbook series to be published by the Bureau of Labor Statistics. The previous volumes were the editions for 1926, 1929, 1931, 1936, and 1941.

In the fullest sense, the preparation of the present volume was a cooperative enterprise, to which the various branches, divisions, and staffs of the Bureau of Labor Statistics contributed. Several other public agencies made data available, as noted in the text and tables. The planning of the coverage and the organization of the facts were directed by Aryness Joy Wickens, Assistant Commissioner for Program Operations, and the volume was coordinated and edited by the Publications Staff, under the supervision of Margaret H. Schoenfeld.

Ewan Clague, *Commissioner.*

Hon. L. B. Schwellenbach,
Secretary of Labor.

Explanatory note 1
Section A: Employment, pay rolls, and unemployment 2
Section B: Labor turn-over 41
Section C: Earnings, hours, and wage rates 51
Section D: Prices and cost of living 104
Section E: Industrial relations 129
Section F: Productivity and unit labor cost 154
Section G: Work injuries 161
Section H: Building and construction 167
Section I: Housing and rents 189
Section J: Social security and related programs 201
Section K: Consumers' cooperatives 204
Section L: Production, income, and expenditures 207

List of Tables by Subject

Section A: Employment, pay rolls, and unemployment .... Page 2

NONAGRICULTURAL EMPLOYMENT 2

Table A-1: Estimated number of wage and salary workers in nonagricultural establishments, by industry division, 1929-47 5

Table A-2: Estimated number of wage and salary workers in manufacturing industries and on contract construction, by State, 1943-47 6

Manufacturing employment and pay rolls 14

Table A-3: Estimated number of wage and salary workers in major manufacturing groups, 1939-47 15

Table A-4: Estimated number of production workers in major manufacturing industry groups, by sex, selected periods 1939-47 17

Table A-5: Indexes of production-worker weekly pay rolls in major manufacturing industry groups, 1939-47 21

Nonmanufacturing employment and pay rolls 23

Table A-6: Estimated number of employees and indexes of weekly pay rolls in selected nonmanufacturing industries, 1939-47 24

Federal personnel 26

Table A-7: Average number of employees in the executive branch of the Federal Government, inside and outside Washington, D.C. (continental United States and elsewhere), 1914-47 27

Table A-8: Number of Federal employees, by branch and agency group (continental United States and elsewhere), 1939-47 28

Table A-9: Personnel and pay in the military branch of the Federal Government (continental United States and elsewhere), 1914-47 30

HIRED FARM EMPLOYMENT AND PAY ROLLS 31

Table A-10: Estimated number of hired farm workers, total and geographic divisions, 1934-47 33

Table A-11: Estimated total farm wages, 1910-47 34

LABOR FORCE AND EMPLOYMENT STATUS 35

Table A-12: Estimated total labor force classified by employment status, 1929-47 36

Unemployment claims 37

Table A-13: Number of continued claims for State unemployment compensation and veterans' unemployment allowances, 1940-47 38

Nonagricultural placements 39

Table A-14: Number of nonagricultural placements by Federal and State employment offices, 1936-47 40

Section B: Labor turn-over 41

Table B-1: Monthly labor turn-over rates (per 100 employees) in manufacturing industries, by class of turnover, 1930-47 42

Table B-2: Monthly labor turn-over rates (per 100 employees) in selected groups and industries, 1940-47 43

Section C: Earnings, hours, and wage rates 51

EARNINGS AND HOURS IN MANUFACTURING AND NONMANUFACTURING 51

Average earnings and hours 51

Table C-1: Average earnings and hours in manufacturing and nonmanufacturing industries, 1932-47 54

Adjusted hourly earnings 87

Table C-2: Estimated average hourly earnings, gross and exclusive of overtime, of production workers in manufacturing industries, 1941-47 89

Table C-3: Estimated distribution of production workers in manufacturing industries, by straight-time hourly earnings, selected periods 1941-47 90

Table C-4: Straight-time average hourly earnings of employees of class I steam railroads, 1921-47 91

WAGE RATES 92

Urban wage rates 92

Table C-5: Percent of change in urban wage rates (manufacturing and selected nonmanufacturing industries), by industry group, selected periods January 1941-October 1947 94

Table C-6: Percent of change in urban wage rates (manufacturing and selected nonmanufacturing industries), by industry group and area, selected periods April 1943-April 1947 95

Section C: Earnings, hours, and wage rates—Continued

Page

Farm wage rates 96

Table C-7: Wage rates of hired farm workers, total and geographic divisions, 1910-47 98

Union scales of wages and hours 99

Table C-8: Indexes of union hourly wage rates and weekly hours in selected industries and trades, 1907-47 100

Table C-9: Union hourly wage rates in selected building construction trades in 37 cities, selected years 1910-47 101

NET SPENDABLE WEEKLY EARNINGS 102

Table C-10: Gross and net spendable average weekly earnings of production workers in manufacturing industries in current and 1939 dollars, 1939-47 103

Section D: Prices and cost of living 104

CONSUMERS' PRICE INDEX FOR MODERATE-INCOME FAMILIES IN LARGE CITIES 104

Table D-1: Consumers' price index for moderate-income families in large cities, by group of commodities, 1913-47 107

Table D-2: Consumers' price index for moderate-income families in 39 United States cities and 4 Territories and Possessions, 1923-47 108

RETAIL PRICES OF FOODS 116

Table D-3: Indexes of retail prices of foods in 22 cities, 1923-47 117

Table D-4: Indexes of retail prices of foods, by group, 1923-47 121

CITY WORKER'S FAMILY BUDGET 123

Table D-5: City worker's budget for family of 4 persons and relative differences in costs in 34 large cities, March 1946 and June 1947 124

WHOLESALE PRICES 125

Table D-6: Indexes of wholesale prices, by group of commodities, 1890-1947 126

Section E: Industrial relations 129

MEMBERSHIP OF LABOR UNIONS 129

Table E-1: Membership of labor unions, 1897-1947 130

EXTENT OF COLLECTIVE BARGAINING 131

Table E-2: Changes in union recognition, 1942-46 133

WORK STOPPAGES 134

Table E-3: Extent of work stoppages, 1916-47 136

Table E-4: Work stoppages in selected industry groups, 1935-47 137

Table E-5: Work stoppages, by major issues involved and duration, 1935-47 138

Table E-6: Work stoppages, by State, 1935-47 140

Table E-7: Work stoppages in 30 cities, selected periods 1939-47 144

Table E-8: Work stoppages, by major union affiliation, 1935-47 145

Table E-9: Work stoppages involving 10,000 or more workers, 1935-47 146

CONCILIATION SERVICE CASES 150

Table E-10: Cases closed by the United States Conciliation Service, fiscal years 1940-41 through 1946-47 151

NATIONAL LABOR RELATIONS BOARD CASES 152

Table E-11: Disposition of cases by the National Labor Relations Board, fiscal years 1935-36 through 1946-47 153

Section F: Productivity and unit labor cost 154

Table F-1: Indexes of output per man-hour (output per worker in agriculture) and unit labor cost for selected industries, selected years 1909-47 155

Table F-2: Indexes of output per man-hour and unit labor cost in selected manufacturing industries, 1919-47 156

Table F-3: Indexes of output per man-hour and unit labor cost in selected mining industries, 1935-47 159

Table F-4: Indexes of output per worker in agriculture, total and 11 farming areas, 1935-47 160

Section G: Work injuries 161

Table G-1: Estimated number of work injuries and resulting time lost, 1940-47 163

Table G-2: Estimated number of work injuries (major manufacturing and nonmanufacturing industry groups), by extent of disability, 1936-47 164

Table G-3: Work-injury frequency rates and indexes of work-injury frequency rates (manufacturing), by extent of disability, 1926-47 165

Table G-4: Work-injury frequency rates for selected manufacturing and nonmanufacturing industries, 1941-47 166

Page

Section H: Building and construction 167

CONSTRUCTION EXPENDITURES 167

[1] Table was in process of revision when Handbook was sent to press and will be supplied later.

Handbook of Labor Statistics
1947 Edition

EXPLANATORY NOTE

In this edition of the Handbook of Labor Statistics—the sixth in a series that started in 1926—the Bureau of Labor Statistics has introduced a number of changes for the purpose of increasing the usefulness of the volume. All of the major statistical series compiled by the Bureau are included. In general, annual data are given for the period beginning before World War I (or from such later time as the series started) through 1947. Monthly figures are also shown for recent periods, including 1947 insofar as available. Results were included for a few nonrecurring Bureau studies that are particularly pertinent to an analysis of labor matters.

To insure the fullest usefulness of the Handbook, selected labor and related economic series have been reproduced that were compiled by other executive departments, boards, and commissions of the Federal Government and by the Board of Governors of the Federal Reserve System.

National averages are supplemented by regional series, such as those by States, groups of States, and by cities, to a wide extent in the tables that make up this Handbook. Unless otherwise stated the general series apply to continental United States only.

Text material consists of definitions of the series and explanations of the coverage of the statistics and the general methods of computation. The descriptions of method are nontechnical in character. Technical descriptions of formulas, weighting, and other methodology used in compiling the Bureau of Labor Statistics series which are included in the Handbook will be furnished, if requested. No analysis of the data was prepared, the purpose of the Handbook of Labor Statistics being to present in one convenient volume a broad selection of economic statistics useful to the individuals and groups studying labor subjects. It is hoped that all groups working in the labor field will find in the Handbook the figures they need when dealing with specific matters.

Provision has been made for continuing usefulness of the volume by the adoption of the loose leaf form. Upon request, insert sheets will be supplied from time to time covering new material and bringing regular series to date. Availability of such inserts will be announced in the monthly list of Publications of the Bureau of Labor Statistics, in the Monthly Labor Review, and in the Monthly Catalog of United States Publications of the Superintendent of Documents. Many of the series are also available currently in the Monthly Labor Review.

The present volume contains an unbound full cover. The full cover may be utilized as a permanent jacket by inserting rings through the punched holes, or it may be severed at the perforation and the printed portion pasted on the outside of a standard 8½ x 11 inch loose leaf binder as an identifying label.

Section A: Employment, Pay Rolls, and Unemployment

A continuing and important function of the Bureau of Labor Statistics of the United States Department of Labor is the compilation of estimates showing the volume of nonagricultural employment. Employer reports and the records of various governmental agencies are the basis of such estimates. The main employment series issued are those for total number of employees in nonagricultural establishments; for manufacturing as a whole and for different industries; and for selected nonmanufacturing industries. Indexes of pay rolls are prepared for manufacturing industries as a whole, for different groups, and for selected nonmanufacturing industries. Employment data by State are compiled for manufacturing industries and for contract construction.

From the Bureau of Agricultural Economics of the United States Department of Agriculture, data are obtained which show the volume of hired farm employment and estimated pay rolls as well as the total number of persons engaged in agriculture. A broader series of statistics—that is, for the labor force, including both agricultural and nonagricultural workers both employed and unemployed—is issued by the Bureau of the Census of the United States Department of Commerce and reproduced here.

Nonagricultural Employment

All persons working for wages or salaries during a specified pay-roll period of each month are covered by the nonagricultural employment estimates compiled by the Bureau of Labor Statistics. The pay-roll period is usually 1 week ending nearest the 15th of the month, because this is the period in the month least affected by such factors as holidays. All persons on the pay roll are included whether or not actually employed in the designated week. Excluded groups are agricultural workers, proprietors, self-employed persons, domestic servants, unpaid family workers, casual workers, and personnel of the armed forces.

Workers who hold two or more jobs at the same time or who change jobs are counted as often in the estimates as they were employed by different employers during the reporting week. Therefore, estimates of the Bureau of Labor Statistics somewhat overstate the volume of employment at any one time. However, persons temporarily absent from their jobs without pay (for example, on strike or on unpaid vacation) are not counted in the estimates.

The employment figures of the Bureau of Labor Statistics provide detailed information on trends and levels of industrial activity. The figures are particularly useful in measuring the trend of activity within a particular industry or group of industries and also give an indication of the magnitude of interindustrial shifts. The estimate for any given industry in terms of numbers of persons actually at work is also useful in connection with series on hours, earnings, and turn-over rates.

The estimates for most industries are based on samples consisting of monthly pay-roll reports voluntarily provided by employers to the Bureau of Labor Statistics. Reports are obtained from all of the larger employers in most industries and from a representative sample of smaller establishments. About 33,500 manufacturing establishments (one-fifth of the total), employing about 8 million workers (60 percent of the total), report employment, pay rolls, and man-hours. For nonmanufacturing industries, in which the average establishment is smaller, considerably less coverage yields statistically adequate estimates.

Less than half of the employers send their reports directly to the Bureau of Labor Statistics and the others report to cooperating State agencies which transmit the statistics to the Bureau.

Each month a tabulation is made comparing the employment in an establishment with that for the previous month. From this comparison, percentage changes in employment over the month are computed. These changes are then linked to form an index. This method is used because firms in the sample may change from month to month, or their reports may be late.

To provide a measure of the number of persons employed at any given time, the index of employment is related to a comprehensive base figure (or bench mark) such as is obtained from censuses of manufactures and business or from the reports of the Federal Security Agency. These data are also used to give each industry its proper weight. Periodic adjustments are needed to take into account new firms. Consequently, when a new base figure becomes available, data for the intervening period are revised to make a continuous series between the two points.

The estimates of employment for certain industries are obtained from sources other than those described above. The most important of these are the United States Interstate Commerce Commission (railroad employees); United States Maritime Commission (water transport personnel); United States Civil Service Commission (Federal employees); and Bureau of the Census (State and local government employees).

Estimates of the number of wage and salaried employees in nonagricultural establishments are shown in table A–1, by industry division. As previously stated, the estimates exclude agricultural workers, proprietors, self-employed persons, domestic servants, unpaid family workers, casual workers, and personnel of the armed forces. All types of establishments are included which hire wage or salaried workers, except those engaged in agriculture or in private households. The classification of any particular establishment into one of eight industrial divisions appearing in table A–1 is determined on the basis of the major product or activity of that establishment in 1939. An establishment that was not in operation in 1939 is classified according to its initial product or activity. The individual establishments of firms engaged in more than one type of activity are classified according to the principal activity of each such establishment. (For example, a concern manufacturing and distributing its own product may have establishments classified in both manufacturing and trade if these activities are carried on in different establishments.)

Employees of firms whose major activity is the performance of construction work on contract are included in the contract construction averages. The contract construction estimates cover all persons employed on and off the construction site. Excluded are employees of nonconstruction organizations (including force-account workers of public bodies and private firms) actively engaged in construction.

Force-account employees are workers hired, not through a contractor, but directly by a business or government agency, and utilized as a separate work force to perform nonmaintenance construction work on the agency's own properties.

The major industry division of trade includes wholesale and retail trade, eating and drinking places, filling stations and automotive repair services, and garages.

The transportation and public utilities group includes interstate railroads, communications, and transportation and utilities of all types except those operated by the Federal Government or by a municipality.

The government estimates include Federal Government employment including manufacturing operations carried on in arsenals and navy yards, and also the employment of State and local agencies. Public education is included in the government estimates; private education is included in the service category. The major industry division—service—includes all types of service establishments and all other nonagricultural establishments not included in the other seven categories. For all segments except the government segment, the employment estimates are adjusted to levels indicated by the Federal Security Agency reports, for years from 1939 through 1946.

Estimates for years prior to 1939 are derived from various Bureau of the Census statistics adjusted insofar as possible for comparability with the estimates from 1939 to date. These estimates are not directly comparable with those obtained from population or household reports because (1) they do not include persons with jobs but not at work unless they are receiving pay; (2) they include persons more than once if such persons had more than one employer during the specified pay-roll period; and (3) they are classified according to the employer's statement of his product or activity which may differ from the classification reported by the respondent in a household survey.

Estimates of the number of employees in manufacturing industries and on contract conconstruction are given by State in table A–2 for 1943–47. The estimates for manufacturing industries cover all wage and salaried workers, but do not add to the national totals as shown in table A–1 because of varying bench mark periods and somewhat different methods of computation used by or for the States. Those for construction include both on- and off-site wage earners and salaried employees of construction contractors.

Work on the development of estimates of employment by State was initiated in January 1945, in response to the need for evaluating the extent and effect of war-induced expansion in manufacturing industries. Varying economic interests in the many sections of the country needed a more detailed knowledge of local change than could be obtained from the national estimates. States were grouped together and regional offices were established to administer this program. The regional offices of the Bureau of Labor Statistics or State cooperating agencies[1] prepared the estimates of employment by State.

Estimates of manufacturing employment by State and by month, made available for the years 1943 to 1947, are shown in table A–2. In addition, the regional offices[2] have released data for other industry divisions as well as more detailed information about manufacturing industries that are important in the respective States.

Estimates of employment on contract construction for 46 States and the District of Columbia have been compiled thus far, as a part of the State employment statistics program, and cover the same period as the manufacturing estimates (see table A–2). Employment information from a representative sample of contractors is related to the data for all contractors in a base month.

The base month data for manufacturing and contract construction were obtained chiefly from records of the unemployment compensation agencies of the respective States, supplemented by records obtained from the Bureau of Old-Age and Survivors Insurance of the Federal Security Agency.

---

[1] State agencies cooperating with the Bureau of Labor Statistics are as follows:

Alabama—Department of Industrial Relations, Montgomery 5.
Arizona—Unemployment Compensation Division, Employment Security Commission, Phoenix.
Arkansas—Employment Security Division, Department of Labor, Little Rock.
California—Division of Labor Statistics and Research, Department of Industrial Relations, San Francisco 3.
Connecticut—Employment Security Division, Department of Labor and Factory Inspection, Hartford 15.
Delaware—Federal Reserve Bank of Philadelphia, Philadelphia 1, Pa.
Florida—Unemployment Compensation Division, Industrial Commission, Tallahassee.
Georgia—Employment Security Agency, Department of Labor, Atlanta 3.
Idaho—Employment Security Agency, Industrial Accident Board, Boise.
Illinois—Department of Labor, Chicago 1.
Indiana—Employment Security Division, Indianapolis 4.
Iowa—Employment Security Commission, Des Moines 8.
Kansas—State Labor Department, Topeka.
Louisiana—Division of Employment Security, Department of Labor, Baton Rouge 4.
Maine—Unemployment Compensation Commission, Augusta.
Maryland—Department of Labor and Industry, Baltimore 2.
Massachusetts—Division of Statistics, Department of Labor and Industries, Boston 10.
Michigan—Department of Labor and Industry, Lansing 13.
Minnesota—Division of Employment and Security, Department of Social Security, St. Paul 1.
Missouri—Division of Employment Security, Department of Labor and Industrial Relations, Jefferson City.
Montana—Unemployment Compensation Commission, Helena.
Nebraska—Division of Placement and Unemployment Insurance, Department of Labor, Lincoln 1.
Nevada—Employment Security Department, Carson City.
New Jersey—Department of Labor, Trenton 8.
New Mexico—Employment Security Commission, Albuquerque.
New York—Division of Placement and Unemployment Insurance, Department of Labor, New York 17.
North Carolina—Department of Labor, Raleigh.
Oklahoma—Employment Security Commission, Oklahoma City 2.
Pennsylvania—Federal Reserve Bank of Philadelphia, Philadelphia 1 (Manufacturing); Bureau of Research and Information, Department of Labor and Industry, Harrisburg (Nonmanufacturing).
Rhode Island—Division of Census and Information, Department of Labor, Providence 2.
Tennessee—Department of Employment Security, Nashville 3.
Texas—Bureau of Business Resarch, University of Texas, Austin 12.
Utah—Department of Employment Security, Industrial Commission, Salt Lake City 13.
Vermont—Unemployment Compensation Commission, Montpelier.
Virginia—Division of Research and Statistics, Department of Labor and Industry, Richmond 21.
Washington—Employment Security Department, Olympia.
Wisconsin—Statistical Department, Industrial Commission, Madison 3.
Wyoming—Employment Security Commission, Casper.

[2] Regional offices of the Bureau of Labor Statistics were reduced to five, effective on July 25, 1947, with headquarters as follows:
Region I—Boston 8, Mass.
Region II—New York 1, N. Y.
Region III—Atlanta 3, Ga.
Region IV—Chicago 6, Ill.
Region V—San Francisco 2, Calif.

[1] Estimates include all full- and part-time wage and salary workers in nonagricultural establishments who worked or received pay during the pay period ending nearest the 15th of the month. Proprietors, self-employed persons, domestic servants, and personnel of the armed forces are excluded. These estimates have been adjusted to levels indicated by Federal Security Agency data through 1946.

[2] Covers all employees of firms whose major activity is construction. The estimates are based on employment reports of these firms and include all off-site employees (regardless of whether or not they are engaged in work relevant to construction activities) as well as employees at the site of construction projects. They do not cover self-employed persons, working proprietors, and employees of nonconstruction organizations (including force account workers of public bodies and private firms) actively engaged in construction activities.

[3] Includes wholesale and retail trade, eating and drinking places, filling stations, automotive repair services, and garages.

[4] Includes all types of service except automotive repair services and all types of nonagricultural establishments not included in any of the other major industry divisions.

[5] Includes Federal, State, and local government including public education and Federal force-account construction.

---

[1] Estimates include all full- and part-time wage and salary workers in manufacturing industries who worked or received pay during the pay period ending nearest the 15th of the month. Proprietors, self-employed persons, domestic servants, and personnel of the armed forces are excluded.

[2] Covers all employees of firms whose major activity is construction. The estimates are based on employment reports of these firms and include all off-site employees (regardless of whether or not they are engaged in work relevant to construction activities) as well as employees at the site of construction projects. They do not cover self-employed persons, working proprietors, and employees of nonconstruction organizations (including force-account workers of public bodies and private firms) actively engaged in construction activities.

[3] Estimates have been adjusted to levels indicated by Federal Security Agency data. Because of varying bench mark periods the State estimates do not necessarily add to the National total.

[4] New series based on 1945 Standard Industrial Classification.

[5] At the date of publication, estimates for this State had not been completed.

[6] The preparation of separate estimates for this State was discontinued after June 1947.

[7] Not available.

Manufacturing Employment and Pay Rolls

Estimates of employment in major manufacturing groups, made by the Bureau of Labor Statistics, are presented in table A–3. In addition to production and related workers (shown in table A–4) the estimates in table A–3 include workers engaged in the following activities: Executive, purchasing, finance, accounting, legal, personnel (includes cafeterias, medical, etc.), professional and technical activities, sales, sales-delivery, advertising, credit, collection, and in installation and servicing of own products, routine office functions, factory supervision (above the working foreman level). They also include employees engaged in new construction and major additions or alterations to the plant who are utilized as a separate work force to perform nonmaintenance construction (force-account construction workers). They exclude proprietors and firm members and the self-employed. As in the table by major industry division (table A–1), the classification is that of 1939 and the changes in employment shown do not reflect for the most part the shift of establishments from one major activity to another during the World War II period. Government-operated establishments manufacturing products for war—such as Government navy yards, arsenals, and ordnance factories—are excluded. The estimates have been adjusted to Federal Security Agency data for all years through 1946.

For a description of the method by which the estimates are made, see page 3.

The estimated number of production workers only for each major industry group in the manufacturing division together with separate totals for male and female workers are shown in table A–4. Table A–5 supplements these Bureau of Labor Statistics employment figures by indexes of production worker weekly pay rolls by major manufacturing groups. Both the current employment and pay-roll estimates are obtained from the same employer reports.

Production workers include working foremen and all nonsupervisory workers engaged in fabricating, processing, assembling, inspection, receiving, storage, handling, packing, warehousing, shipping, maintenance, repair, janitorial, watchman services, product development, auxiliary production for plant's own use (e. g., power plant), and record-keeping and other services closely associated with the above production operations. Excluded are supervisory employees (above the working foreman level) and their clerical staffs, routemen, salesmen, and certain other groups of employees. Prior to 1945, production workers were identified as wage earners.

The pay-roll figures are restricted to production workers in manufacturing industries and to nonsupervisory employees in nonmanufacturing industries. If employers report the wages and salaries of the selected group of employees for a pay-roll period that exceeds 1 week, the data are reduced or converted to a 1-week basis. The statistics include pay for sick leave, holidays, and vacations taken during the pay period reported, and also overtime pay and shift differentials. Bonuses are excluded unless earned and paid regularly in the pay period, as is also retroactive pay not earned during the pay period reported. Deductions are not made for pay-roll taxes.

As the sample reports collected by the Bureau of Labor Statistics cover only one pay period of each month and the Federal Security Agency reports cover all of the wages and salaries paid to all employees during the quarter, the former series cannot be adjusted directly to the latter. Instead, the pay-roll adjustment is made by applying the same ratios to the pay-roll series as are applied to the employment series (described on page 3).

TABLE A-3: Estimated number of wage and salary workers in major manufacturing groups, 1939-47[1]

[In thousands]

Period	All manufacturing	Durable goods—total	Iron and steel and their products	Electrical machinery	Machinery except electrical	Transportation equipment, except automobiles	Automobiles	Nonferrous metals and their products	Lumber and timber basic products	Furniture and finished lumber products	Stone, clay and glass products
1939 average	10,078	4,357	1,171	355	690	193	466	283	465	385	349

---

[1] Estimates include all full- and part-time wage and salary workers in manufacturing industries who worked or received pay during the pay period ending nearest the 15th of the month. These estimates have been adjusted to levels indicated by Federal Security Agency data through 1946. In addition to production and related workers the estimates include workers engaged in the following activities: Executive, purchasing, finance, accounting, legal, personnel (includes cafeterias, medical, etc.), professional and technical activities, sales, sales-delivery, advertising, credit, collection, and in installation and servicing of own products, routine office functions, factory supervision (above the working foreman level). They also include employees engaged in new construction and major additions or alterations to the plant who are utilized as a separate work force (force-account construction workers).

[1] Data have been adjusted to levels indicated by Federal Security Agency data through 1946. Production workers include working foremen and all nonsupervisory workers engaged in fabricating, processing, assembling, inspection, receiving, storage, handling, packing, warehousing, shipping, maintenance, repair, janitorial, watchman services, product development, auxiliary production for plant's own use (e.g., power plant), and record-keeping and other services closely associated with the above production operations. Supervisory employees above the working foreman level and their clerical staffs, route-men, salesmen, and certain other groups of employees are excluded. Prior to 1945 the production worker group was identified as "wage earner" group.

[2] Figures are derived from 1939 Census of Manufactures, Persons Employed in Manufacturing Establishments, by Sex, Washington, August 1941.

TABLE A-5: Indexes of production-worker weekly pay rolls in major manufacturing industry groups, 1939–47[1]

[1939 = 100]

Period	All manufacturing[2]	Durable goods	Nondurable goods	Iron and steel and their products	Electrical machinery	Machinery, except electrical	Transportation equipment, except automobiles	Automobiles	Nonferrous metals and products	Lumber and timber basic products	Furniture and finished lumber products
1939 average	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0
1940 average	114.5	125.1	104.1	121.3	127.9	130.6	188.8	126.4	125.8	109.7	108.7

---

[1] See footnote 1, table A-4. The indexes of production worker pay rolls are based upon reports covering the wages paid to production workers during the week ending nearest the 15th of each month. They include pay for sick leave, holidays, and vacations taken during the pay period reported and also include overtime pay and shift differentials. They exclude bonuses unless earned and paid regularly in the pay period. They also exclude retroactive pay not earned during the pay period reported. When adjustments are made in the employment series similar adjustment is made in the accompanying pay-roll series, since no data exist to which the pay-roll series may be directly adjusted.

[2] Pay-roll indexes for manufacturing industries in 1909*, 1914*, and 1919–38 (1939 = 100) follow:

Year	Index	Year	Index
1909*	33.9	1928	109.8
1914*	40.1	1929	117.1
1919	103.9	1930	94.8
1920	124.2	1931	71.8
1921	80.2	1932	49.5
1922	86.0	1933	53.1
1923	109.1	1934	68.3
1924	101.8	1935	78.6
1925	107.3	1936	91.1
1926	110.5	1937	108.9
1927	108.5	1938	84.7

*Based on data from the U. S. Bureau of the Census.

Nonmanufacturing Employment and Pay Rolls

The estimated number of employees and the indexes of weekly pay rolls in table A–6 covering selected nonmanufacturing industries were derived in the same manner as the manufacturing series in tables A–3 and A–5. An exception is that of class I steam railroads.

The figures of employment and weekly pay rolls for class I steam railroads are derived from data published by the United States Interstate Commerce Commission. Employment and pay-roll data as used herein are limited to employees classified and reported on an hourly basis (excluding most of the executive, professional, and supervisory employees). The Interstate Commerce Commission up to 1932 reported only the number of employees on the pay rolls at the middle of the month and thereafter also the number on the pay rolls during the month. The average of the substantially constant ratios from 1933 to 1937 was used to estimate the number on the pay rolls during the month from 1921 to 1932. The Commission's data as published for 1921 and 1922 include class I switching and terminal companies. Detailed figures by class of employees include switching and terminal companies to 1927 and exclude these companies thereafter. Beginning in 1923, however, employment and pay rolls of all workers and of workers on an hourly basis were published, both including and excluding switching and terminal companies. On the basis of the almost constant ratios after 1922, switching and terminal companies (accounting for hardly more than 1 percent of total employment and pay rolls) were excluded for the years 1921 and 1922.

TABLE A-6: Estimated number of employees and indexes of weekly pay rolls in selected nonmanufacturing industries, 1939–47

[1939 = 100]

Period	Mining[1]

---

[1] Data are for production and related workers only and are adjusted to levels indicated by Federal Security Agency data through 1946.

[2] Does not include well drilling or rig building.

[3] Includes all land-line employees except those compensated on a commission basis. Excludes general and divisional headquarters personnel, trainees in school, and messengers.

[4] Includes private and municipal street-railway companies and affiliated, subsidiary, or successor trolley-bus and motor-bus companies.

[5] Money payments only; additional value of board, room, uniforms, and tips, not included.

[6] Data are for production and related workers only.

[7] From United States Interstate Commerce Commission, Wage Statistics of Class I Steam Railroads in the United States (currently published on a monthly and annual basis in Statement No. M-300). Limited to employees classified and reported to the Interstate Commerce Commission on an hourly basis (excluding most of the executive, professional, and supervisory employees). The number of employees is the number on the pay rolls during the month, averaged for the annual series.

Similar figures, available for class I steam railroads for the period from 1921 to 1938, are given below. (Minor adjustments were made in the published Interstate Commerce Commission's figures for 1921 to 1932 for comparability with later figures.)

Period	Employment (in thousands)	Weekly pay-roll index (1939 average = 100)
1921 (July–Dec.)	1,745	....
1922	1,691	144.6
1923	1,945	166.2
1924	1,829	154.6
1925	1,819	156.7
1926	1,858	161.7
1927	1,808	159.0
1928	1,719	152.9
1929	1,726	157.7
1930	1,535	136.9
1931	1,290	110.8
1932	1,052	78.8
1933	998	73.9
1934	1,031	80.5
1935	1,017	87.3
1936	1,104	99.1
1937	1,143	107.0
1938	955	92.7

Federal Personnel

Estimates of Federal employment and pay rolls and military personnel and pay (including allowances) are published regularly by the Bureau of Labor Statistics. Agencies in the executive branch supply data through the United States Civil Service Commission. The legislative and judicial branches and Government corporations supply their data directly to the Bureau of Labor Statistics. Statistics covering the military are furnished by the War Department (Army), the Navy Department (for the Marine Corps as well as the Navy), and the Treasury Department for the Coast Guard. (In wartime, the Coast Guard is a part of the Navy and figures for it are reported by the Navy Department.) Persons outside the United States and in continental United States are covered by the totals shown below.

The employment in the executive branch of the Federal Government, in table A–7 for 1914–47, is shown separately for Washington, D. C., for other areas, and as a total.

In table A–8, the total number of Federal employees is shown by branches for 1939–47. (Data on pay rolls were under revision when the Handbook was sent to press.) In addition to separate totals for the executive, legislative, and judicial branches and Government corporations, total employment is given separately for defense agencies, the Post Office Department, and all other agencies of the executive branch.

Personnel and pay in the military branch of the Federal Government are shown in table A–9. The information on the number of persons in the armed forces covers 1914–47. For the various elements of pay the time coverage varies; the pay-roll totals are given beginning with 1934, and mustering out pay, family allowance, and leave payments are given from the date of authorization.

TABLE A–7: Average number of employees in the executive branch of the Federal Government, inside and outside Washington, D.C., 1914–47[1] (continental United States and elsewhere)

Period	Average number employed		
	Total[2]	Wash., D.C.[3]	Other areas
1914	501,039	35,500	465,539
1915	494,624	36,459	458,165
1916	498,597	37,509	461,088
1917	581,276	43,447	537,829
1918	1,014,975	138,626	876,349
1919	931,677	127,240	804,437
1920	669,243	91,012	578,231
1921	578,546	79,137	499,409
1922	544,080	70,229	473,851
1923	534,203	66,525	467,678
1924	541,344	64,374	476,970
1925	551,028	64,018	487,010
1926	547,313	61,080	486,233
1927	545,518	60,068	485,450
1928	554,783	61,662	493,121
1929	575,343	63,637	511,706
1930	590,075	68,009	522,066
1931	603,531	71,626	531,905
1932	599,486	68,673	530,813
1933	604,387	69,618	534,769
1934	690,904	88,809	602,095
1935	790,335	104,010	686,825
1936	862,907	115,437	747,470
1937	867,896	113,427	754,469
1938	868,032	115,976	752,056
1939	935,493	123,773	811,720
1940	1,042,898	136,672	906,226
1941	1,393,783	178,540	1,215,243
1942	2,252,359	258,284	1,994,075
1943	3,138,838	278,363	2,860,475
1944	3,292,607	263,787	3,028,820
1945	3,525,638	249,948	3,275,690
1946	2,660,879	232,333	2,428,546
1947	2,107,945	207,800	1,900,145

[1] Data are from monthly reports of the Civil Service Commission beginning in 1929. Data for prior years were secured by taking employment as of June 30 as reported in Annual Reports of the Civil Service Commission, and making any necessary adjustments to make the data conform in coverage and definition with data reported later. For adjustments to data of individual agencies, see footnotes 1 and 4, table A-8.

[2] Emergency relief workers are excluded; ordinarily they are considered as unemployed. For the number of persons on such projects and their pay, see table J-1.

[3] Beginning with 1942, data cover, in addition to the District of Columbia, the areas in Maryland and Virginia which are included by the Bureau of the Census in its definition of the Washington, D.C., metropolitan area.

TABLE A-8: Number of Federal employees, by branch and agency group, 1939–47[1] (continental United States and elsewhere)

Period	Number employed (as of first of month)							
	All branches	Executive[2]				Legislative	Judicial	Government corporations[5]
		Total	Defense agencies[3]	Post Office Department[4]	All other agencies

---

[1] Data for the executive branch are reported through the Civil Service Commission; data for the legislative and judicial branches and Government corporations are reported directly to the Bureau of Labor Statistics. Through June 1943, employment reported for the executive branch included that outside continental United States. Beginning July 1943, employment outside continental United States was excluded from the figures reported monthly and was reported separately only in January, April, July, and October. Employment for months between the reporting periods was estimated and added to the continental United States totals.

[2] Data for Federal force-account construction are included; for definition, see page 3.

[3] Covers the War Department, the Navy Department, Maritime Commission, National Advisory Committee for Aeronautics, the Panama Canal, and, until their abolition or amalgamation with the peacetime agencies, the agencies created specifically to meet World War II and reconversion emergencies.

[4] Prior to December 1943, employment data were adjusted upwards to convert the temporary substitute employees from a full-time equivalent to a name-count basis in order to be consistent with data reported subsequently. Prior to July 1945, clerks at third-class post offices were hired on a contract basis and, therefore, because of being private employees, are excluded here. They are included beginning July 1945, however, when they were placed on the regular Federal pay roll by congressional action. Substitute rural mail carriers, who have been included in data published by the Civil Service Commission since September 1945, are excluded here. Employment figures include fourth-class postmasters in all months. Additional employment necessitated by the swollen Christmas business is included in December of each year; it is excluded from published figures of the Civil Service Commission beginning December 1942.

[5] Current data cover the following corporations: Federal Reserve banks, banks of the Farm Credit Administration, and the Panama Railroad Co. Data for earlier years include at various times the following additional corporations: Inland Waterways Corp., Spruce Production Corp., and certain employees of the Federal Deposit Insurance Corp. and of the Office of the Comptroller of the Currency, Treasury Department.

TABLE A-9: Personnel and pay in the military branch of the Federal Government, 1914–47[1] (continental United States and elsewhere)

Period	Personnel (in thousands) average for year or as of first of month[1]			Total pay for year or for month (in thousands)

---

[1] For years prior to 1918, totals are from the National Bureau of Economic Research, The National Income and Its Purchasing Power; the break-downs for Army and Navy are estimated. From 1918 through 1939 for the Army and from 1918 through 1933 for the Navy, data are from Annual Reports of the War and Navy Departments. Later data are from monthly reports received directly by the Bureau of Labor Statistics from the various military branches. The totals in this table vary somewhat from those included by the Bureau of the Census in the total labor force (see table A-12 because of differences in the time of month to which the series refer and differences in classification of personnel. The Census figures refer to the week containing the eighth of the month from January 1944 through September 1946; the Bureau of Labor Statistics figures are for the first day of the month. The Census series excludes persons on terminal leave; the Bureau of Labor Statistics totals include such persons.

[2] Data exclude the pay of retired personnel and inactive reserves. For the Navy proper and Coast Guard, data include cash payments for clothing allowances in January, April, July, and October. Pay rolls are not available prior to 1934. Except for Army data for 1943–April 1947, and Coast Guard data for all years which represent actual payments, pay rolls are computed from personnel records.

[3] Data represent the amount expended during the month.

[4] Covers Government's contribution only; the men's share is included in the pay rolls.

[5] Leave payments were authorized by Public Law 704 of the 79th Congress to enlisted personnel discharged prior to September 1, 1946, for accrued and unused leave and to officers and enlisted personnel then on active duty for leave accrued in excess of 60 days. Beginning September 1, 1946, payment of personnel while on terminal leave is included in the pay roll. Value of bonds (representing face value to which interest will be added at the time bonds are cashed) and cash payments are included.

Hired Farm Employment and Pay Rolls

First-of-the-month estimates of the number of hired farm workers in the United States and for nine geographic divisions are published by the Bureau of Agricultural Economics of the United States Department of Agriculture for the period from 1925 on.

Collection of monthly farm employment data through crop reporters was started in October 1923. In 1938, a National Research Project of the Work Projects Administration developed and published monthly farm employment estimates for 1925 to 1934 from the crop reporter data. Current monthly estimates have been made by the Bureau of Agricultural Economics from crop reporter data from 1939 to the present time, using the methods developed in the Work Projects Administration survey. When data from the 1940 Census became available, the series was adjusted to the census benchmark data and monthly estimates were made for January 1935 to 1939.

Each crop reporter gives for his own farm the number of hired workers doing 2 or more days' work, excluding housework, during the week of the inquiry. Seasonal variation in the number of hired farm workers is considerable. The months of January and July—which are generally the low and peak months of hired farm employment—have been selected for inclusion in table A–10, to illustrate the extent of seasonal variation. The data received from the crop reporters probably do not fully reflect the seasonal variation because (1) the sample of crop reporters' farms includes a disproportionate number of larger than average farms, (2) these farms carry on a more stable type of farm operation than is usual, and (3) some reporters may report only full-time workers and omit all or part of the seasonal workers. Adjustments, however, are made to allow for this understatement of seasonal variation.

From 17,000 to 21,000 farmers report each month. The Census of Agriculture reported 5,859,169 farm operators in the United States in 1945.

The average number of hired workers per farm for States are computed for the reporting farms. The averages are then adjusted by factors which are based on the last census level, labor requirements data, and the estimated seasonal pattern of employment based on the 1940 Census and studies in selected States. The adjusted averages are then multiplied by the estimated number of full-time farms in each State to obtain the estimated number of hired workers employed.

Employment data from crop reporters were not collected during most of the period 1910–24. The annual estimates given for those years are based on Census employment data and such factors as acreage and production of crops, number of livestock, and farm population changes. The annual employment figures for the years 1925–47 are averages of the first-of-the-month estimates.

The annual average of hired farm employment generally constitutes only about a fourth of total farm employment and is concentrated on a small portion of the Nation's farms, mainly large-scale commercial enterprises. The remaining three-fourths of total farm employment is composed of farm operators and unpaid family workers. The proportion of hired farm employment varies extensively by season and by region. For example, in 1935–39 the annual average of hired farm workers in the Nation as a whole comprised 25 percent of total agricultural employment; the range was from 14 percent in the East South Central region to 45 percent in the Pacific. In contrast, in January of the same period hired farm employment averaged 19 percent of the total; the range was from 12 percent in both the East and West North Central regions to 35 percent in the Pacific region.

Since data contained in the Handbook of Labor Statistics are primarily concerned with wage earners, the figures showing the number of farm family workers, including farm operators and unpaid family workers, have been excluded. The employment of this group is included in the tabulations of the crop reporters and is published monthly by the Bureau of Agricultural Economics with the data on the number of hired farm workers.

The estimated number of hired farm workers in the United States and for nine geographic divisions covering 1934–47 are given in table A–10.

Estimates of the total expenditures of farm operators for hired farm labor beginning in 1910 are also published annually by the Bureau of Agricultural Economics. The total farm wage bill is the sum of cash wages and the value of perquisites paid by farmers to hired farm labor. All three series are shown in table A–11, by years, 1910–47.

The annual estimates of the cash expenditures for hired labor for census years were taken from the Census of Agriculture. Estimates for intercensal years were based on changes in hired farm employment and average wage rates. The estimates of both wage rates and the number of hired farm workers were based on crop-reporter data (discussed on pp. 31 and 96).

The estimates of board and lodging furnished hired farm workers as perquisites in 1910 and 1920 were based on totals from the corresponding Censuses of Agriculture. Estimates for intervening and subsequent years were based on the percentage change in the product of the number of hired farm workers paid monthly and daily wage rates with board and the value of board and lodging. This value was estimated as the difference between wage rates with board and wage rates without board, as estimated from crop-reporter data.

The value of perquisites other than board and lodging for 1925 was derived from a special Bureau of Agricultural Economics study. Estimates of their value for other years were based on 1925 data and on the change in hired farm employment and changes in farm prices of the major perquisite items. The total perquisite estimates were adjusted to the levels shown by the May 1945 Survey of Wages and Wage Rates in Agriculture, made by the Bureau of Agricultural Economics.

The product of farm wage rates and employment may overstate the total cash wage bill. First, the wage rates used are probably not representative of wage rates paid all hired farm workers, as discussed in connection with table C–7. Second, the multiplication of wage rates by the number of hired farm workers employed 2 days or more during the week assumes full-time employment. These calculations have been made, however, merely to derive figures for intercensal years. The series as a whole is tied to Census enumerations which may underestimate to some extent the total cash wage bill. This possible downward bias is not believed to be serious and is probably uniform throughout the series.

TABLE A–10: Estimated number of hired farm workers, total and geographic divisions, 1934–47

[1] Monthly figures are as of the first of the month.

[2] For earlier years the estimated numbers of hired farm workers (in thousands) follow:

1910—2,877
1911—2,870
1912—2,889
1913—2,905
1914—2,919
1915—2,934
1916—2,966
1917—2,933
1918—2,841
1919—2,784
1920—2,883
1921—2,901
1922—2,915
1923—2,894
1924—2,874
1925—2,871
1926—3,027
1927—2,950
1928—2,956
1929—2,984
1930—2,850
1931—2,690
1932—2,498
1933—2,433

TABLE A–11: Estimated total farm wages, 1910–47

[In millions]

Labor Force and Employment Status

The only official estimates of total labor force, employment, and unemployment are issued by the Bureau of the Census. Under the census definitions—

The labor force includes persons 14 years of age and over who are employed or unemployed during the census week (the week containing the 8th day of the month).

Employed persons are those who (1) work full or part time for pay or profit, (2) work without pay in a family enterprise (farm or business) at least 15 hours; or (3) have jobs, but do not work because of illness, vacation, labor-management dispute, bad weather, or layoff with definite instructions to return to work within 30 days.

Unemployed persons include those who are not employed, but are looking for work. Also included are persons who would be looking for work except that (1) they were temporarily ill, (2) they expected to return to jobs from which they had been laid off for an indefinite period, or (3) they believed no work was available for them in the community. Persons engaged on public emergency work projects were also included as unemployed during the period when such projects were in operation.

Estimates of labor force, employment, and unemployment beginning with 1940 are based on a sample survey of the population conducted each month by the Bureau of the Census. The sample included in 1947 approximately 25,000 private households living in 68 areas which include 125 counties and independent cities in 42 States and the District of Columbia. The households in the sample are visited each month by Census enumerators to obtain information on the labor force status and other population characteristics of members of the household.

The unemployment estimates of the Bureau of the Census are not directly comparable with the published totals of unemployment compensation claims and claims for veterans' readjustment allowances. For example, certain persons such as farm laborers and government workers are not covered by the unemployment compensation system. Also there are certain groups of persons who might file claims for unemployment compensation, but would not be counted as "unemployed" under the definition of the Bureau of the Census, e.g., persons with jobs but temporarily not working because of bad weather.

In addition, the employment data of the Census differ from employment estimates of the Bureau of Labor Statistics and the Bureau of Agricultural Economics based on reports from business establishments or farms. For example, the Census estimates of nonagricultural employment, unlike those of the Bureau of Labor Statistics, include self-employed, proprietors, domestic servants, and unpaid family workers. In addition, persons with jobs but not at work are included in the Census employment totals; in contrast, only part of this group is likely to be included in employment figures based on establishment pay-roll reports.

Of the annual average estimates of total labor force,[3] civilian labor force, employment, and unemployment shown in table A–12, those for the period 1929–39 were prepared by the Bureau of Labor Statistics to provide a historical series. These estimates are on a basis comparable in concept with that of the Bureau of the Census in its current monthly series.

---

[3] For Bureau of Labor Statistics data on the number of persons in the armed forces, see table A–9.

TABLE A-12: Estimated total labor force classified by employment status, 1929–47

Period	Number (in thousands)			
	Total labor force[1]	Civilian labor force	Employment	Unemployment
1929 average	49,440	49,180	47,630	1,550
1930 average	50,080	49,820	45,480	4,340
1931 average	50,680	50,420	42,400	8,020
1932 average	51,250	51,000	38,940	12,060
1933 average	51,840	51,590	38,750	12,830
1934 average	52,490	52,230	40,890	11,340
1935 average	53,140	52,870	42,260	10,610

---

[1] Total labor force consists of the civilian labor force and the armed forces. However, about 150,000 persons in the armed forces in April 1940 who were stationed outside continental U.S. and who were not enumerated in the 1940 Census of Population are excluded from the total labor force. Figures since 1940 have correspondingly been reduced by 150,000 for purposes of comparability. For explanation of differences between Census armed forces totals and those of the Bureau of Labor Statistics, see table A-9, footnote 1.

[2] Data for week ending March 30, 1940.

[3] Beginning in June 1947, the estimates are presented rounded to the nearest thousand. Because of rounding the individual figures do not necessarily add to the group totals.

Unemployment Claims

A continued claim under the State unemployment-insurance system is defined by the Bureau of Employment Security of the United States Social Security Administration as follows: "An application for waiting-period credits or benefits which certifies to the completion of a waiting-period week or a benefit period. There are two categories of continued claims: (1) waiting-period claims and (2) compensable claims. A waiting period is a 1- or 2-week period usually required only once during a benefit year, even though the worker may be out of work and entitled to benefits more than once during that time. Waiting-period claims do not result in benefit payments. A compensable claim is filed for each additional week of insured unemployment after a worker has completed his waiting period."

A continued claim under the system of veterans' readjustment allowances is "a claim for unemployment allowance for a completed week of unemployment filed under the veterans' unemployment allowance program."

The number of continued claims shown in table A–13 cover both the waiting-period claims and compensable claims under the State unemployment-compensation systems and the veterans' unemployment allowance claims under the GI Bill of Rights (Public Law 346, 78th Cong., 2d sess., approved June 22, 1944), for the period 1940–47.

The data on continued claims filed monthly or annually provide a measure of the volume of operations under the State unemployment compensation and veterans' unemployment allowance programs, but do not directly measure the number of separate claimants. For example, an individual worker may file as many as four or five continued claims during a calendar month.

NOTE: For information on social security operations including unemployment see Section J, p. 201.

Nonagricultural Placements

Statistics of the number of nonagricultural placements by Federal and State employment offices, which were furnished by the United States Employment Service of the Department of Labor and are shown in table A–14 covering 1936–47, do not indicate the total volume of hiring at any given time. They represent the placements made from among such workers as apply at public employment offices for assistance in obtaining jobs. Moreover, certain placements are excluded as indicated in footnote 2, table A–14.

Section B: Labor Turn-over

Labor turn-over rates published by the Bureau of Labor Statistics cover manufacturing (from January 1930), mining (from March 1943), and telephone and telegraph industries (from July 1943). As the fluctuations in employment in highly seasonal industries overshadow the turn-over characteristics of nonseasonal industries, such industries as fertilizer manufacturing in the chemical group and canning and preserving in the food group are excluded.

The turn-over series are based on reports furnished by 6,700 cooperating establishments which employ about 4.5 million workers. Separate series are issued showing turn-over rates for each type of personnel action—total separations, quits, discharges, lay-offs, miscellaneous (including military) separations, and accessions. For each specific type of turn-over, the rate is the number of persons involved during the calendar month per 100 persons on the pay roll in the week ending nearest the 15th of the month.

Beginning with the January 1943 rates, the labor turn-over data pertain to wage and salaried workers rather than to wage earners only as in previous years. From June 1943 through August 1945, total separation, quit, and accession rates were compiled for men and women in selected war industries. From September 1945 through July 1947, these rates for men and women have been computed for the major industry groups.

In October 1945, the number of employees who actually worked in, or were paid for, the pay period ending nearest the 15th of the month was adopted as the employment base. The midmonth base replaced the average employment base which had been used in computing monthly turn-over rates from January 1930. In a test using more than 5,000 reports for which both average and midmonth employment figures were available, the Bureau of Labor Statistics found that for industry as a whole the change in base had little effect on the rates.

To compute the turn-over rate, the number of separations or accessions which have occurred in a plant or group of plants during the course of a month is divided by the total number of employees who worked during, or received pay for, any part of the pay period ending nearest the 15th of that month. The result so obtained is multiplied by 100. For example, in an establishment 1,250 employees worked during, or received pay for, the week of January 12–18. From January 1 through January 31, 110 employees were separated for all causes. The total separation rate is:

$$\frac{110}{1250} \times 100 = 8.8.$$

NOTE: The "net turn-over rate" (discontinued in November 1934) is the accession rate, or the separation rate, whichever is lower in the month concerned. The same information may be obtained by comparison of the published accession and separation rates.

The annual rate (discontinued in 1941) is the sum of the 12 monthly rates for each type of turn-over. The annual rate should not be confused with the equivalent annual rate (discontinued in August 1931) which is an adjustment in the monthly rate to eliminate the fluctuation caused by differences in the length of the calendar month. The equivalent annual rate may be computed by dividing the rate for the calendar month by the number of days in the month and multiplying by the number of days in the year.

Monthly labor turn-over rates (per 100 employees) are shown in table B–1 for manufacturing industries as a group for 1930–47 and in table B–2 for selected groups and industries for 1940–47.

TABLE B-1: Monthly labor turn-over rates (per 100 employees) in manufacturing industries, by class of turn-over, 1930–47[1]

[1] Turn-over rates for certain seasonal industries such as canning and preserving are not included. From April 1943, the printing and publishing industries have been excluded. Beginning in January 1943, labor turn-over data cover wage and salaried workers; for previous periods, they refer to factory workers only. From January 1943 also, manufacturing firms reporting labor turn-over have been assigned industry codes on the basis of products currently made.

[2] Prior to 1940, miscellaneous separations were included with quits. From September 1940, military separations have been included with miscellaneous separations.

TABLE B–2: Monthly labor turn-over rates (per 100 employees) in selected groups and industries, 1940–47[1]

---

[1] Turn-over rates for certain seasonal industries such as canning and preserving are not included. From April 1943, the printing and publishing industries have been excluded. Beginning in January 1943, labor turn-over data cover all employees; for previous periods they refer to factory workers only. From January 1943, also, manufacturing firms reporting labor turn-over have been assigned to industry groups on the basis of products currently made.

[2] Data for previous years are not strictly comparable.

[3] Less than 0.05.

[4] Not available.

[5] Industry group rates based on incomplete returns.

Section C: Earnings, Hours, and Wage Rates

A substantial part of the work of the Bureau of Labor Statistics has been devoted to the collection and analysis of wage and related hours data. The chief comprehensive and continuous measures of the changes in earnings and hours of production and related workers in both manufacturing and nonmanufacturing industries are those showing gross average weekly earnings, average weekly hours, and average hourly earnings. The gross hourly earnings series for manufacturing industries adjusted for overtime payments for hours in excess of 40 per week has been used as the basis for adjusted hourly earnings, in recent years, to meet growing needs for such information. Another series shows the distribution of workers in manufacturing industries by their straight-time hourly earnings. Data on the trend of average weekly earnings also are the basis for the calculation of average spendable earnings.

In the collection of wage-rate data, as distinguished from earnings, the Bureau of Labor Statistics has long been active. During World War II, the preparation of semiannual series was undertaken which show general indexes of urban wage rates in manufacturing and in selected nonmanufacturing industries. The wage-rate index was calculated to meet the need for a measure which is unaffected by changes in the length of the workweek, in the amount of premiums for overtime and night work, and by various kinds of changes in the geographic and industrial location and skill of workers—all of which enter into statistical series on earnings that are computed from reports on employment, man-hours, and total pay rolls. Union scales of wages and hours in highly organized trades have been collected annually for several decades and provide national and city data on an occupational basis.

Straight-time hourly earnings of railroad workers that are presented are those published by the Interstate Commerce Commission and the wage rates shown for hired farm labor are compiled by the United States Department of Agriculture.

Earnings and Hours in Manufacturing and Nonmanufacturing

Average Earnings and Hours

Averages of weekly earnings, weekly hours, and hourly earnings of workers are published monthly by the Bureau of Labor Statistics for manufacturing and selected nonmanufacturing industries. The figures for manufacturing, mining, and laundries relate to production workers only. Data for the other industries are for all employees unless otherwise noted. In the construction industry, however, the average hours and earnings figures cover all types of site employees of the reporting contractors, such as foremen, time clerks, skilled workers, helpers, apprentices, and common laborers. The averages apply to employees engaged in privately financed construction at the site only.

Production and related workers include working foremen and all nonsupervisory workers (including lead men and trainees) engaged in fabricating, processing, assembling, inspection, receiving, storage, handling, packing, warehousing, shipping, maintenance, repair, janitorial, watchman services, product development, auxiliary production for plant's own use (that is, power plant), and record-keeping and other services closely associated with the production operations listed. Excluded are supervisory employees (above the working foreman level) and their clerical staffs, routemen, salesmen, and other groups of employees mentioned on page 14.

The nonsupervisory employee classification is not intended to cover persons in high-salaried positions, and therefore omits proprietors and firm members, officers of corporations, and other principal executives. The group includes all other employees, both full- and part-time, who worked or received pay for any part of the period reported. Included are employees on paid vacation during the pay period covered but excluded are members of the armed forces, pensioners, and others carried on rolls in a pay or nonpay status but not working during the period. Slight variations exist between industries, depending upon the type of operations.

The durable- and nondurable-goods groups are best defined by reference to the major groups which make up the totals (see table A-3).

The types of payments included in the reports on pay rolls are wages and salaries before deductions (for social security, taxes, etc.). Commissions are included in the wholesale and retail trade, insurance, and brokerage reports. Wages paid for sick leave, holidays, and vacations during the pay period covered by the report are included, and sick, holiday, and vacation hours paid for are included in the man-hour figures. Cash payments in lieu of vacations not taken are excluded, as are bonuses (unless paid regularly each pay period) and payments made as a result of retroactive wage adjustments. No allowance is made for payments in kind.

Approximately 31,000 establishments employing more than 7 million workers are included in the sample for manufacturing. For the nonmanufacturing industries, the samples vary. In retail trade—one of the more important industries—reports cover 25,000 establishments with 650,000 employees. The establishment coverage is somewhat less than that used in the estimates of employment (see page 2).

By questionnaire, reporting firms are asked to supply employment, pay-roll, and man-hour data for the pay period ending nearest the 15th of the month. This pay period was selected to eliminate from the pay period reported, insofar as possible, the influence of such factors as national holidays.

The Bureau of Labor Statistics requests information on the total number of employees in the reporting establishment and, in addition, on the number of production or nonsupervisory workers and their total wages and aggregate hours. These data relate to a week or pay period; if a period other than a week is reported, pay rolls and man-hours are converted to a weekly basis. Tabulations are then made by industry, and the averages of hours and earnings for individual industries are computed directly, as follows: Pay rolls divided by employment yield average weekly earnings; pay rolls divided by man-hours yield average hourly earnings; man-hours divided by employment yield average hours per week. The average resultant weekly hours figure is affected by absenteeism, turn-over, and similar factors, as the employment figure includes all persons working at any time during the pay period. The average hours do not refer to scheduled hours of work.

The weekly earnings are not necessarily the product of the average hours per week and the gross average hourly earnings because some plants do not report man-hour data.

In the average weekly earnings series, a measure is provided of the money-wage income of those workers covered. The average hourly earnings series indicates changes in employers' labor costs per man-hour. In industries in which piece work is common, the averages are affected by changes in production per man-hour as well as by changes in rates. Overtime payments are reflected in the averages for all industries.

For the 20 major manufacturing groups, for the durable- and nondurable-goods divisions, and for all manufacturing industries combined, weighted averages are obtained as follows: In computing the weighted group average of hours worked per week, the average for each of 133 individual industries is weighted by the estimated number of production workers in that industry; in deriving the hourly earnings, the earnings for each industry are weighted by estimates of the total number of hours worked in that industry for the week covered. The weekly earnings average for each group is obtained by multiplying the weighted average of weekly hours by the weighted average of hourly earnings. Consequently, shifts in employment and changes in hours of employment influence the averages for the groups and for all manufacturing.

Average weekly earnings, average weekly hours, and average hourly earnings are shown in table C-1 for manufacturing industries as a group, for the durable- and nondurable-goods groups, and for individual manufacturing industries. The data for nonmanufacturing industries are given for individual groups only. The time coverage of the different series is 1932–47, with a footnote statement added which gives the all manufacturing averages for selected periods from 1909 through 1931.

For construction, the table presents average hours and earnings data only for total privately financed, on-site building construction for the years 1934 through 1939. Additional data became available in 1940, making it possible to provide separate averages for certain special trades contractors. Nonbuilding construction (highways, bridges, tunnels, dams, etc.) is included beginning with February 1946.

The averages for class I steam-railroad employees are derived from Interstate Commerce Commission data. Coverage is for employees classified on an hourly basis (excluding most of the executive, professional, and supervisory employees). The derivation of the data on employment and pay rolls is described on page 23.

The Interstate Commerce Commission publishes a number of series of man-hours and of compensation, and it reports the number of employees at the middle of the month and the number receiving pay during the month. The computations of average hours and earnings presented in table C–1 are derived from total pay rolls, total man-hours paid for, and the number of employees who receive pay during the month. Since railroad transportation is carried on continuously throughout the year, the total man-hours are reduced to a weekly basis by dividing the annual or monthly totals of man-hours by 365, 366, 30, 31, 28, or 29 and multiplying by 7. Average weekly earnings are computed by multiplying average hourly earnings by average weekly hours, conforming to the computation of averages for major industry groups in other series, as described above.

TABLE C–1: Average earnings and hours in manufacturing and nonmanufacturing industries, 1932–47[1]

---

[1] These figures are based on reports from cooperating establishments covering both full- and part-time employees who worked or received pay during any part of one pay period ending nearest the 15th of the month. For manufacturing, mining (including crude petroleum production), power laundries, and cleaning and dyeing industries, the data relate to production and related workers only. For the remaining industries the data relate to all employees except high paid executives and officials. Exceptions are noted.

[2] For earlier years the averages are as follows:

Year	Average weekly earnings	Average weekly hours	Average hourly earnings (Cents)
1909	$ 9.84	51.0	19.3
1914	11.01	49.4	22.3
1919	22.08	46.3	47.7
1923	23.82	45.6	52.2
1924	23.93	43.7	54.7
1925	24.37	44.5	54.7
1926	24.65	45.0	54.8
1927	24.74	45.0	55.0
1928	24.97	44.4	56.2

Year	Average weekly earnings	Average weekly hours	Average hourly earnings (Cents)
1929	$25.03	44.2	56.6
1930	23.25	42.1	55.2
1931	20.87	40.5	51.5

[3] Average hourly earnings (in cents) for certain key dates are as follows:

	August 1939	January 1941	October 1942
All manufacturing	62.4	68.3	89.3
Durable goods	68.8	74.9	99.0
Nondurable goods	57.6	61.0	75.1

[4] To prevent misinterpretation of the average of 121.7 cents for those workers who were employed in February 1946, it is not inserted in the table. The increase from 116 9 to 121.7 cents per hour does not measure the increase awarded when the steel strike was settled. Maintenance workers were kept on during the strike, while low-paid production workers were on strike. Since hours and weekly earnings are normally used only to interpret what has happened to those people who were employed, these figures are shown but should be used with caution.

TABLE C–1: Average earnings and hours in manufacturing and nonmanufacturing industries, 1932–47[1]—Continued

MANUFACTURING—Continued

Period	Iron and steel and their products—Continued																	
	Malleable-iron castings			Steel castings			Cast-iron pipe and fittings			Tin cans and other tinware			Wirework			Cutlery and edge tools
